I do not think it good practice to keep the atmosphere dry and hot during the flowering period. If everything else is right you will get as good a set if the ordinary routine of damping is carried on and the temperature not increased; at least you will have less red spider by this method.

I have very little faith in the artificial aids generally recommended to assist Vines in setting a good crop, unless it be in the case of such sorts as Alnwick Seedling, where the reproductive organs are of peculiar and unusual construction; though I have seen this variety set thicker than any Hamburgh by a simple daily tap to the rods. It is wise, however, to assist in such cases, and I know of nothing better or speedier than a good-sized feather duster, which should be gently drawn over the bunches when in flower once a day. If the right material is not in the wood and buds the previous autumn, all the foxes' or rabbits' tails in the world will not give a good set. It is a very silly plan, and one often adopted with shy setting varieties, to leave all bunches on the Vine till after the flowering period, so that a better selection can be had if the set is bad. If a horse cannot draw one ton up a hill, it will not be likely to succeed any better with five tons. If your Vines will not set one dozen bunches, how do you think they will set five dozen? All bunches should be removed to at least one on a shoot as early as possible, and this on other kinds as well as shy setters. If your Vines appear healthy, but do not set well or go wrong at the finishing, lift their roots. I know a house 80 feet long that was planted with a mixed selection, including Muscat of Alexandria and Canon Hall. It cropped well for a few years; then, though the Vines did not make gross wood, they failed to set satisfactorily, shanked and shrivelled badly at finishing. The inside border was turned out, all roots taken up, half of the soil mixed with fresh, and put back and the roots relaid. This was all, and only the work of a few days. The following crop was splendid. The Muscats, both Canon Hall and Alexandria, which were the worst before, were now the best—perfectly set, no shrivelling, large, well-coloured berries, and not one shanked in the lot. An example is shown in the illustration (fig. 76).

Another important point is the best style of training to adopt. The close pruning single rod system, which is almost universal, I do not think the best. A method which allows the Vine to extend and occupy a larger space each succeeding year is not only the more natural way of training, but heavier crops and finer fruit can be maintained over a longer period, with less expense, in this way than the usual method. I have seen a bad case of shanking cured in one season by this extension system. A few Vines of Gros Colman were planted at one end of a span house. These were trained up the usual way and stopped at the top. They were inclined to grow strong, and the fruit shanked badly. Two leaders were allowed to grow from each, and trained down the other span, and left at pruning time the full length, or about 12 feet. They broke well and regular, and bore a splendid crop of large-berried bunches, and not one shanked. I am confident that for private establishments, as well as market, where a house is often devoted to one kind, much better results would be

FIG. 76.—MUSCAT GRAPES.
THE RESULT OF BORDER RENOVATION.

obtained if one Vine filled the whole house. I have thought of a method whereby this could be done and not lose space while the Vine was extending.—D. BUCHANAN.

[The excellent photograph by Mr. Buchanan not only shows a well-shaped Muscat bunch, good thinning, and fine even-sized, well-finished berries, but also shows that he provides ample space between the laterals for the free development of foliage under the direct action of light, and thus, with otherwise correct treatment, insures leaves which make the most and the best of the materials supplied by healthy roots freely working in suitable soil. But even thinly disposed leaves cannot be of the best if a faulty method of ventilation is pursued by the abuse of front sashes during critical periods of growth. Mr. Buchanan's remarks on this subject (page 386) last week are in our opinion worthy of attentive consideration. We have more than once observed that those cultivators who grow the heaviest crops of Grapes, and make the most of them by sale, are those who admit the least amount of air through side ventilators; some admit none at all in that way, for the sufficient reason that moveable front sashes or slides are dispensed with in their vineries.]

(To be concluded.)

I AM glad Mr. Buchanan has called attention in last week's *Journal of Horticulture* to top ventilation. It is a matter which I wrote about long ago in the *Journal*. In the very last range of houses erected under my supervision each horticultural builder sending in plans showed bottom ventilation. This was struck out from the plan selected, but I had the ridge ventilation made to open separately on each side. This is a simple matter, the importance of which is known to all good gardeners; yet each builder showed back and front ridge ventilators to open together!—EDWARD LUCKHURST.

THERE is much that is sound and practical in Mr. D. Buchanan's "Profitable Fruit Growing," but it would be interesting to know something about the style of his vineries, and whether his advice is intended for southern as well as northern growers. I allude more especially to his remarks on ventilation. I have jotted down to-day (9th May) a few notes as to what has happened, and as I am not yet too old to learn I will ask Mr. Buchanan to tell us how he would have acted under the circumstances. I did not quite follow my own plan during the early part of the day, being anxious to travel with Mr. Buchanan as far as I safely could.

The day has been a typical spring day, more like April than May. It has been comparatively mild, with intervals of sunshine and passing cloud, and a little rain late in the afternoon. It was the sort of day so frequent during spring when you cannot tell what to expect during the next few minutes, and consequently it is not safe to go far away from the houses for any length of time. I do not say that Mr. Buchanan's advice is not correct for Scotland. I have no means for knowing that, having never practised further north than Liverpool, and of course the climate, and it may be the houses, are very different.

My remarks will be confined to one span-roofed compartment, 30 feet wide, with the roof at an angle of 35°, and one side facing south-west. It has ventilators, which are equal to a continuous opening of 18 inches on each side of the ridge, and upright sashes on each side at the bottom, which open continuously to fully the same width. This is more ventilation than most houses have, but I find it is often all required. My notes are as follows:—

5 A.M.—West wind, mild, some clouds, unsettled. Temperature of house 60°. Stopped fire.

7 A.M.—Shade temperature 65°. Opened top ventilators on leeward side half up.

9 A.M.—Shade temperature 70°. The same ventilators opened to their full extent, and the house damped down rather heavily.

10.30 A.M.—Shade temperature 77°. Opened top ventilators on windward side half up.

11.45 A.M.—Shade temperature 82°. Opened top ventilators to their fullest extent.

12 NOON.—Shade temperature 86°. Opened bottom ventilators on the leeward side to their fullest extent, when the temperature soon after rose to 90°.

4 P.M.—Rain clouds were threatening, and the wind increasing in force. Temperature had fallen to 75°. All ventilators were closed with the exception of the top ones on the leeward side, which were left up about 6 inches, and were finally closed at 6 P.M. From breakfast time till four o'clock the pipes were only about as warm as new milk.

I think Mr. Buchanan will see that it would be difficult to carry out his plan of ventilating here even on a mild spring day; it, of course, would be more so on a hot summer day. Even during the month of May I have sometimes had not only all the ordinary ventilators open, but the doors as well, before ten o'clock in the morning.—WM. TAYLOR, Bath.

[Our remarks above apply to a few acres of vineries within twenty miles of London. Our friend basks in the sunshine of Bath. His observations are, all the same, pertinent.]

HARMFUL AND HARMLESS GARDEN MOTHS—20.

DURING the month of May we notice that caterpillar life is in full activity, and hosts of these insects feast upon the young foliage or blossoms, also on the stems and roots that are rich with the juices of the spring. Now it often happens that when we are turning them out of their retreats, should we come upon them, we find caterpillars almost close together which have quite a different history. One has, perhaps, hatched from an egg laid early in April, and has fed up rapidly; the other is a survivor of the autumn, and its caterpillar life will be about eight months. Some have fancied that those which have hibernated exhibit in the spring heartier appetites than the insects of the new year; this is certain, that they stand the rough weather of the vernal season better, as a rule, than their juvenile companions not long from the egg.

Varied are the habits of insects even in the same group, and a few of the Noctua moths deposit eggs in autumn which do not hatch till spring. It might be advantageous to destroy these, but they are not easy to discover. The largish moth called the ranunculus (*Polia flavocincta*) appears in October, and the eggs then laid remain unhatched till April. It has often been noticed near London and in South England; probably it is a welcome morsel sometimes to a hungry sparrow. I do not see that the English name is particularly applicable, for the insect does not resemble the flower in its general aspect. But it has upon the greyish upper wings, which are mottled with brown, a row of six orange spots, on each of which is a black arrowhead pointing to the base; there are also four orange streaks near the middle of each wing. The caterpillar evidently starts in April upon Chickweed and Groundsel, but feeds later upon Mints, Thrift, and other garden herbs. It is velvety, green, sprinkled with white dots, having a narrow black stripe along each side, and enters the earth in July.

Another moth in the above genus, which, for a wonder, is commoner in Ireland than England, though it occurs about most of our

counties, if not plentifully, is the grey chi (*Polia chi*), a smaller species, white, or whitish grey, with various dark markings, one especially, resembling the Greek letter. A curious type of this moth, taken in the West, is of olive green colour, having white spots. The caterpillar hatches in spring from autumn eggs, eating Sallow or Hawthorn chiefly, something else at times; thus, in the Midlands, it has been caught defoliating the familiar Tea Tree, *Lycium barbarum*. In its green hue it resembles the larger caterpillar described above, a similar black stripe appears, but instead of dots two broad white stripes, and some black rings.

Hawthorn hedges furnish food to the caterpillar of the green brindled crescent moth, *Miselia Oxyacanthæ*, one frequent near London, and now feeding, but owing to the body being nearly the colour of the twigs, it frequently escapes notice; a hump, however, adorns the last segment, and there are a few white dots. The moth flies in September, hiding by day amongst shrubs. Over the reddish brown ground colour of the wings are sprinkled metallic green scales, and there is the crescent mark not uncommon amongst Noctuas; here it is pure white. One ranunculus moth has been mentioned; there is another, less in size, absent from many English counties, but plentiful in some localities. As its caterpillar chiefly feeds on the flowers and seeds of the garden Lettuce, it is one of our foes. This small ranunculus (*Hecatera dysodea*) appears during July, and is dark grey, marbled with light grey, and brown or black, specially distinguished, too, by scattered orange spots. The caterpillar is dull green, or now and then yellowish, having faint black stripes; it has a trick of suddenly dropping from its food to the earth if any person comes near, so often escaping.

We have in the genus *Dianthœcia* a little group of moths, several of which occur about gardens. They are notable for the fact that the caterpillars mostly live upon the pods of some species of *Lychnis* or *Silene*. The females generally have a long egg-placer, by which they insert eggs into the flower buds they select. One of the well-known species is the tawny shears, *D. carpophaga*, a variable moth, sometimes almost white, at other times a dark bistre brown, or of intermediate tints, but usually showing the two discoidal spots, set in a bar or band across the wings. During June eggs are deposited upon some *Campion*, the young caterpillar soon enters, and having consumed the unripe seeds of one flower head travels to another, keeping on at this until it has attained a good size; then it descends to the earth by day, and mounts at night, when it may be discovered with a lantern, the head buried in a pod, and the body very visible outside; this is smooth and plump, greenish grey, marked with broad white stripes. About eight months is spent by this species in the chrysalis state.

Another moth, called the lychnis, or *D. capsicola*, is rather like its relative, but the colour of the wings is generally brown, on which are the pale spots and some grey lines. It flies during summer. The caterpillar occurs in August or September on *Campions* or *Catchflies*, leaving conspicuous holes. From its mode of feeding when nearly adult, it must be an easy prey for birds. The body is slender and smooth, the head shining, but the body dull; on each segment is a mark, shaped like a V, of dark brown; in the middle of it is a small bar. The marbled coronet (*D. conspersa*) has a mark upon the thorax, thought to resemble a crown; the wings are smoky black, marbled and spotted with white. Less common than the preceding, it is scattered over Britain, but rare in Ireland. Its caterpillar prefers the head of the *White Champion* and *Ragged Robin*, concealing itself within these while it can. This also has the V-shaped markings on each segment, which are joined by a line running through them.

Both as a moth and caterpillar I think the majority of gardeners know the angle shades, possessor of the lengthy Latin name of *Phlogophora meticulosa*. The latter means "fearful;" but the insect is not particularly timid, only the caterpillar tucks in its head if alarmed, as do many others, sometimes forming a complete ring. Of course, the English name comes from the central mark of brown on the greyish-green fore wings; the under wings are rather pinkish. The thorax is conspicuous from its high ridge and long hair, which stands out like a ruff. This is one of the moths that has usually two broods yearly. In May and June we see the early brood—specimens are frequent on walls or trunks of trees; the second appears in September or later, developed from caterpillars of the summer. The moths now coming out are produced by caterpillars which, having hibernated, fed up during April. The cocoon is slight, and formed on the surface of the soil. In colour these caterpillars are of two shades, green or brown; both varieties are sprinkled with whitish dots. The head is small, and the body gradually enlarges towards the hinder segments.

We have, too, a small angle shades of a rich umber brown, somewhat similarly marked, but the bar across the wings has a large white spot. This is *Euplexia lucipara*, and flies in the summer. The caterpillar lives upon Ferns, especially the common *Brake*, during autumn. Its colour approaches that of its favourite food, being a delicate green above and paler beneath; along the back are faint black markings.

Mr. Wood enters in his book on our garden foes the handsome moth called the Marvel-du-Jour (*Agriopis Aprilina*), one distributed throughout Britain, flying in October and again in spring. He states that the Apple often suffers from the attacks of the caterpillar, which goes below during the day, hiding in the grass or herbage, then mounts the branches after sunset. There appears to be some mistake; we almost invariably find it on Oak, and I have never received specimens, or any complaint about its doings, since my connection with this journal. The moth is pale green, conspicuous from the black and white markings on the ground colour. It has been taken in gardens near woods. The caterpillar has a black cross on the face, and along the green or grey body a series of lozenge-shaped spots. Allied to this is the large dark moth called the great brocade (*Aplecta occulta*), which turns up occasionally in all English counties during the summer. Its caterpillar feeds on various low plants, such as the Primrose and Periwinkle, in spring. Probably from its striking colours of reddish brown and white it is apt to be seized by insect-hunting birds.—ENTOMOLOGIST.

PALMS.

FOR decorative purposes on ceremonial occasions of various kinds, also for balls, concerts, festivals, corridors, staircases, pedestals, or wherever stateliness with elegance in effect is desired, no plants can bear the least comparison with tall Palms. Their deep green arching leaves have a refreshingly cool appearance, however great the heat may be, while a tropical aspect is imparted such as no other plants can produce. No doubt Tree Ferns are imposing, and in demand for various functions, but light as the individual fronds may be in the aggregate as composing the "heads," they have a dense appearance as compared with the opener leafage of Palms, through which the light plays freely, throwing dappled shadows everywhere.

A few of the taller Palms most in demand are *Seaforthia elegans*, which is particularly stately, but not so easily kept in good condition as the *Kentias*, and of these *Kentia australis* is strikingly handsome in a large state. Of similar character but less towering in growth is *Kentia Fosteriana*, and still less so is the perhaps greatest in demand of all Palms, *Kentia Belmoreana*. For producing an effect of airy lightness by its few slender leaves rising to a height of 15 or 20 feet, more or less, *Cocos flexuosa* is unique, but is by no means found in such great abundance as *Kentias*. Extremely elegant when 10 to 15 feet high is the distinct and pleasing kind *Dæmonorops palembanicus*. For massiveness in a large state or small, the Fan Palm, *Latania borbonica*, has no equal, and has to be grown in hundreds of thousands to meet the demand. The leaves are broad, bright, shining green, and form the foundation of millions of "Fans," which are dressed to taste. There is also a soft yellow-leaved variety, though still comparatively scarce, which associates effectively with other kinds.

The demand for Fan Palms for ordinary room decoration is enormous, the plants ranging from 18 inches to 2 feet high. But most in demand of all, as what may be termed a domestic Palm—seen almost everywhere, on street barrows and in the homes of the multitude—is the previously mentioned *Kentia Belmoreana*. The extent of glass ranges devoted to the raising of plants of this popular species is astonishing. It would be a task to count the plants in one establishment, such as Mr. Thomas Rochford's, for example, where there can scarcely be less than a million. Hundreds of thousands of plants are sold for a shilling each, but the price, of course, varies with the size.

Equally useful, hardy, and easy to manage as a room Palm, also most elegant, is *Phoenix rupicola*. This species, though far less plentiful than the preceding, and therefore not obtainable at equal prices, are raised in large numbers to meet an ever growing demand. Plants, if properly attended to, will remain healthy and ornamental in an ordinary living room for years. One could be specified which has passed through ten summers and winters in a dwelling in the suburbs of London. Though a native of India this Palm is proving surprisingly hardy, though less so than its congener from the Cape of Good Hope, *Phoenix reclinata*, of which a plant is now healthy in the position it has occupied in a room for twenty years.

As elegant table Palms, and employed as such in pots varying from 3 to 5 inches in diameter, the extremely slender *Cocos Weddelliana* from South America is the most extensively provided. The leaves are almost of grass-like elegance, yet stout and persistent, and rich glossy green. It has been a favourite for years, as it will be for years to come. Almost equally slender, dwarfer, and hardier, is a small Brazilian species, *Geonoma gracilis*. It is, in fact, what its name implies, one of the most graceful of all, and its production seems only to be limited by the supply of seed obtainable.

Practically all Palms are raised from seeds sown in warm structures. Being monocotyledons, the first growths are grass-like, the natural character developing with age. Until comparatively recent years almost the whole of the Palms sold in England were raised on the Continent, chiefly in Belgium. The importation of plants into England was continuous. The times have changed. Not only can all the millions of Palms required in this country be raised in it, grown as well, and sold as cheaply as plants raised elsewhere, but many thousands are exported to other lands. By their decoration with home-grown plants ocean steamers became floating advertisements. British enterprise did the rest, and England was made a great nursery of Palms.—A BRITISHER.

WEATHER IN LONDON.—Though we have had a fair amount of sunshine during the past few days, we have also had a good proportion of rain. On almost every day there have been more or less heavy showers, especially on Thursday, Friday, and Sunday. On Monday it was fine, but the sun only shone brightly at rare intervals. On Tuesday there were occasional showers, but on Wednesday it was fine.

— WEATHER IN THE NORTH.—Very heavy rains fell on the 3rd and 4th; since then the weather has been generally seasonable, and some days particularly fine, Saturday and Sunday being delightfully pleasant, but somewhat colder in the evenings. Monday, also fine, closed with a coldish easterly wind, which continued on Tuesday morning.—B. D., S. Perthshire.

— CAMPANULA ISOPHYLLA ALBA.—This plant is excellent for hanging baskets and to grow in pots for standing in front of stages. The flowers, which are white, are produced in great profusion from the extremities of the drooping shoots. The blooms last a considerable time. As the flowers fade pick them off, which will enhance the appearance of the plants, and prolong the display.—E. D. S.

— ISLE OF WIGHT.—After the recent rains vegetation in all parts of the Island has moved with great rapidity. This morning (May 7th) I received from a Yarmouth friend a sample of new Potatoes (*Sharpe's Victor*) dug outside. On a south border, or under favoured conditions, early Potatoes can be had; but for those in the open there is still a danger of "Jack Frost."—S. H.

— EARLY LAXTON POTATO.—This variety is largely grown for first early cropping on a south border at Coombe Court. Mr. Springthorpe speaks of it in warm terms. Those who remember the remarkable tuber crops produced from its short sturdy tips in two successive trials at Chiswick a few years since, can easily understand this appreciation. But it is surprising all the same to find how little the variety is either known or grown; yet it promised to make one of the earliest tuberizing, dwarfest topped, white flattish Potatoes in commerce. A large grower at Mitcham used to have it in great quantity, and spoke of it in high terms. I should regard it as one of the very best for either pot or frame culture to be found. All the same, that may not have been general experience. With all these very precocious Potatoes so much depends on how the seed tubers are wintered.—WANDERER.

— PRIMROSES CHANGING COLOUR.—Is it really a fact that wild Primroses do change colour? Is it not much more probable that flowers have become fertilised with pollen carried in the air, or by some insect, from flowers of garden Polyanthus or Primroses; that seed has ripened and been shed, then has grown and produced seedling plants, the flowers of which are coloured, or rather discoloured? The Primrose does not naturally cast its seed wide. Rather because of the habit of contraction found in the stems, the seed vessels, before the seed is ripe, curl down close under the leafage. Some manage to grow, and the seedlings come up, perhaps, in doing so, crowding out the old plants, and thus young plants take the place of old ones unsuspectingly. I have never seen a case in which the original wild Primrose plant has changed the colour of its flowers, but seedlings in gardens constantly do so.—A. D.

— STRAWBERRY ROYAL SOVEREIGN.—Mr. Springthorpe of Coombe Court, Kingston Hill, rather reminds me of the famous individual who appears so frequently in certain soap advertisements. Our gardener friend, since he has begun to grow Royal Sovereign in pots for forcing, grows no other. What high tribute to the merits of this comparatively new variety is this! The old Biblical saying is in its case materially reversed, for blessed is the variety when all men speak well of it, and that is certainly the case with Royal Sovereign. The variety sets well, carries and swells its fruit well, gives rich colour, and, especially when finished in cool houses and with ample ventilation, delicious flavour. The crop I saw the other day from plants producing single crowns only was a first-rate one, and if grown for market should be a good paying one. Reference to the market value of the fruits leads naturally to the question of value the variety may have been to its raiser, the late Mr. Laxton. It has proved to be one of the finest and most valuable Strawberries ever introduced.—WANDERER.

— **EXTENSION OF PREMISES.**—Messrs. B. S. Williams & Son, of Upper Holloway, have acquired extensive grounds, forming part of the Manor Farm, Regent's Park Road, Finchley, for the purpose of further extending their business, and growing hardy trees, shrubs, general nursery stock, and plants under glass.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of the Society, to be held in the rooms of the Royal Astronomical Society, in the Quadrangle of Burlington House, Piccadilly, W., on Wednesday, the 18th inst., at 4.30 P.M., the following papers will be read:—"The Frequency of Rainy Days in the British Islands," by Robert H. Scott, M.A., F.R.S.; "The Abnormal Weather of January, 1898," by Frederick J. Brodie, F.R.Met.Soc.

— **WOLVERHAMPTON HORTICULTURAL CLUB.**—There was a numerously attended fortnightly meeting of this enterprising Society on the 3rd inst., Mr. Simpson presiding, when Mr. James Deans (Messrs. John Pope & Son, Birmingham) gave a most interesting lecture on the history and culture of the Iris, illustrated by coloured plates and drawings of several of the choicer species and varieties. Unfortunately it was too early in the season for a display of cut specimens, excepting, perhaps, the few earlier blooming kinds. The lecture was listened to with close attention, and in the ensuing discussion one of the speakers humourously remarked that one or two sceptical acquaintances of the fraternity had remarked to him that they did not think it worth while to be at the trouble of going to listen to a description of "blue Flags," but had they come no doubt they would have been convinced of the contrary, and have cause to admire and reflect.—W. G.

— **DEATH OF MR. A. SIMPSON.**—On the 4th inst. the death occurred of a well known citizen of York—viz., Mr. A. Simpson, head of the firm of Messrs. A. Simpson & Sons, Heworth Nurseries, of whom it may be said that from small beginnings he had made for himself a prominent position amongst the nurserymen of the county. He was associated with the Ancient Society of York Florists, amongst whom (as well as a wide circle of acquaintances) he was highly respected. His connection with the Society extended from the year 1868, and for a great part of the time he served on the Committee, having filled the office of Steward three years, and in 1894 occupied the position of Chairman of the Executive, the most successful (financially) year in the Society's annals. He was a prominent figure at the York Chrysanthemum shows since their beginning, having charge of the arrangements for the vegetable exhibits, no light duty, as those who know the quantity to deal with could testify. The more immediate cause of the end was a paralytic seizure. The interment took place on the 7th inst. at York Cemetery, being preceded by a service at St. Thomas' Church, the chaplain (Rev. H. Vyvyan) taking a part, many of the deceased's colleagues being present. He was in the sixty-eighth year of his age, and leaves a widow, three sons and two daughters.—J. L.

— **WINTER-FLOWERING PELARGONIUMS.**—In your note at page 388 you say, "It is comparatively seldom one sees a really first-class collection." Doubtless you were here referring more to culture and blooming than to mere variety. Seeing this note induced me to refer to Mr. Parker's paper, in which he gives what can be described as an exceedingly restricted list of varieties, whether double or single, suitable for winter culture. At Swanley, where may always in midwinter be seen a superb show of single and double Pelargoniums in bloom, and really a marvellous sight, not only are all the summer blooming varieties practically reproduced, but there are scores of them. Really, I have seldom found any good flowering summer variety that would not under ordinary culture flower equally well in the winter. It is needful to say so much to disabuse minds of a popular error. Then your mention of the comparative scarcity of winter-flowering collections naturally turned my thoughts to the singularly beautiful one which Mr. Salter provides for his employer, Mr. Haywood, at Woodhatch, Reigate, every winter. A span house is devoted entirely to these Zonal Pelargoniums, all single, and the sight of brilliant floral colouring to be seen is one calculated to stagger and surprise anyone. I have often marvelled that similar beautiful shows were not common. Now I noted last November the best varieties in great variety of colour at Woodhatch. There are two dozen recorded, and all different from any mentioned by Mr. Parker. Richer colours, finer pips, more luxuriant florescence no other varieties could excel. If the plants could have been carted to the Drill Hall they would have made the sensation of the season. All were in 6-inch pots; all from cuttings made at the end of the previous January, grown, pinched from time to time, stood outdoors to harden, ceasing pinching end of August, plants got under glass in September, then allowed to come away and bloom as I saw them.—VISITOR.

— **TOMATOES FOR PLANTING OUT.**—Tomatoes in 5 or 6-inch pots for outdoor culture must be kept in cool airy positions near the glass, so as to insure them being kept sturdy.—E.

— **PRICKING OUT HALF-HARDY ANNUALS.**—To secure good plants at bedding-out time which will give the best results it is necessary that seedlings which may be crowded in seed pots or boxes be transplanted in fresh soil in a frame or boxes. Asters, Stocks, Marigolds, Scabious, Carnations, Zinnias, Salpiglossis, Phlox Drummondii should receive this attention.—E. S.

— **PONTEDERIA CRASSIPES.**—This plant flowered last autumn in the Lily tank at the Oxford Botanic Garden, and now again its flowers are displayed therein. Probably only a limited number of those who have cultivated this plant have ever succeeded in flowering it, so that the circumstance of its repeated blooming at Oxford at so short an interval, and thus early in the season, would appear to be deserving of recording in the Journal.—J. E. J.

— **ISLE OF WIGHT ROSE SOCIETY.**—At the annual meeting of the above Society recently held at Newport, and presided over by Sir Barrington Simeon, Bart., M.P., the Financial Secretary stated that the total receipts for 1897 were £71 15s. 11d., and the expenditure £59 3s. 3d., leaving a credit balance of £12 12s. 8d. It was decided to hold this year's show at Carisbrooke Castle (by permission of H.R.H. Princess Henry of Battenberg) on June 16th. Sir Barrington Simeon was unanimously re-elected President of the Society.

— **APRIL WEATHER AT HODSOCK PRIORY.**—Mean temperature of the month, 46.9°. Maximum in the screen, 66.7° on the 8th; minimum in screen, 25.5° on the 5th; minimum on the grass, 15.1° on the 5th. Number of frosts in the shade, six; on the grass, eighteen. Sunshine 116 hours, or 28 per cent. of the possible duration. Rainfall, 2.50 inches; rain fell on thirteen days; maximum fall, 1.22 on the 11th. Rainfall from January 1st 5.12, diff. from average 1.73. A mild month, with heavy fall of rain on Easter Monday. The last few days wet.—J. MALLENDER.

— **YELLOW POLYANTHUSES.**—I notice that the yellow variety referred to as John Wilkinson is by "N. N." termed a Primrose. Mr. Arnott gives it its proper designation—Polyanthus. It is a pity everyone does not understand the undoubted distinctions that exist between one and another. A true good yellow Primrose I have never seen. Even the double yellows are pale creamy things, falsely called yellow; yet I have raised scores of thousands from seed of true Primroses of all the colours I could obtain. Probably if some readers had had my experience of yellow Polyanthus they would make less fuss over any variety. They are common enough, although now I never see such grand orange yellow hose-in-hose Polyanthus as I used to have at Bedford. But of ordinary yellows of the finest form, richest colour, and thrum-eyed, too, there are plenty. I saw great masses of seedlings the other day at Long Ditton, from which I could have selected scores of splendid yellows, and I longed to select the wheat from the tares, but it was not my business. I should have liked "N. N." to have seen the grand show of these Polyanthus I saw the other day at Farnham.—A. D.

— **BLACKS IN TOMATOES.**—If by this term "N. N." means the black blotches so commonly found on and about the flower points of Tomatoes, I fear his suggestion as to the cause hardly meets the case. How frequently does it happen that this black spot or blotch is seen on the under sides of the fruit to which the sun's rays hardly get access. An odd circumstance I noticed in looking through some Tomato houses recently was that whilst spot was very rare on the red varieties, it was so common on a yellow variety of high repute that few fruits were left sound. But the disease no doubt begins in the flower, where, in moisture probably, the fungus gets possession, and proceeds, after destroying the blooms, to extend to the fruit. That seems to be the only explanation of its common appearance near or exactly on the flower points of the fruits. It is a disease which once it is found seems to admit of no healing. Nothing remains but to pull the fruits and to destroy them. If any remedy is to be found at all it would seem to be needful of application whilst the bloom is open. Possibly dustings of sulphur, or creating sulphur fumes by coating the pipes with sulphur paste or similar dressing, may do good. In any case there is much need for a more complete elucidation of the true nature of the disease and its remedies, if any are to be found. Sprayings of Bordeaux mixture are easily advised, but because so dangerous on Tomatoes, not desirable remedies. The production of sulphur vapour may be much less so. One thing is very certain in relation to Tomatoes under glass; it is that if warmth is maintained, they can hardly have too much ventilation.—D.

— **LOADS OF POTATOES.**—Potatoes are sold by the load throughout the West Riding of Yorkshire. A load weighs 18 stones (14 lbs. to the stone); 9 loads to the ton.—*S. Yorks.*

— **PROGRESS.**—We had a pleasant surprise by post this morning. An old friend in a new form—or, rather, in a more approachable form. Paper knives are always to hand when wanted, and the leaves of the *Journal* are so tantalising—the most interesting part inaccessible. But now that day is over, and the good old paper, with its charming contents, is neat and trim as a bevelled-edged book. Perhaps this is a small matter; but no matter should be small which so much enhances the comfort of the reader.—*THE MISSUS.*

— **DWARF BEAN SION HOUSE.**—Until this spring I have not proved this old variety, and feel sure there are many beside myself unacquainted with its merits. The newer hybrid kinds now so universally chosen have given the older sorts a poor place, but the variety under notice, according to my experience, deserves special mention. It has been equal to any other I have grown in pots, and set its crop with greater freedom than some others. The pods, too, are of good size and colour, and the habit of the plants very compact. It certainly is a variety that might give a good account of itself if growers gave it an opportunity.—*R. A.*

— **TARRAGON.**—The list of herbs given by "E." page 369, does not include this, and as it is very rarely offered by seedsmen; this, perhaps, explains the reason. I have only found it offered by one seedsman, and my present stock was obtained in this way. True, Tarragon can be divided easily, and is of free growth, but cases sometimes arise when seeds would be invaluable. In severe weather it has a risk of being destroyed, and herein lies the value of seeds. It is customary, where this herb is much used, to lift some roots in the autumn, place them in boxes of soil under glass. These, in spring, can be used in renewing the plantation.—*WILTS.*

— **VINE MILDEW.**—I observe Mr. D. Buchanan's practical theory respecting cold draughts being a prolific means for the production of mildew, referred to on page 386, and of the wholesome dread some cultivators have of this insidious affection, red spider included also. I should like to say in corroboration that I had a forcible illustration when on a visit to Drayton Manor, Tamworth, the fine old seat of Sir Robert Peel, Bart., one day in September last, of a simple means adopted by Mr. James Mack, the then able and persevering gardener, to preclude the admission of air through the front ventilators or sashes of the well-cropped vineries, so great was his horror of the presence especially of mildew. The means in question was simply a thick lining of lawn mowings or other similar material banked against the sashes outside, thus forming a complete barrier to the ingress of cold air, and on no occasion during the season of growth was air admitted artificially excepting through the top ventilators. Thus by the means indicated the Vines had enjoyed an immunity from mildew. Furthermore, the almost total, if not quite, absence of red spider characterised the healthy condition of the Vines at the period of my visit. I may add that the Peach houses at Drayton Manor bore evidence of the thoroughly practical and intelligent system adopted in the management thereof, as well as the creditable state of the gardens and grounds altogether.—*W. G., Birmingham.*

— **HORTICULTURE AND COOKERY.**—The Dean of Rochester has written on this subject as follows in reference to a book which we have not seen:—"The subjects of horticulture and cookery are of great national, social, and moral importance. We would magnify their influence wherever the opportunity presents itself, and to the full extent which the circumstances will allow among all classes of the community. We would induce the farmer to renovate those miserable collections of dead and dying trees which in so many instances he calls his orchard. We would have him restore the old waste places which he calls his garden, and would give to every cottager who desires to have it a sufficient space for vegetables, fruit, and flowers, instruct him in the selection of the fittest, and teach his wife to cook. If a man does not find happiness at home he will seek it elsewhere in vain; but when, after his day's work is done, you refresh his eyes and his palate with the result of his own handiwork, you do much to make him satisfied with his surroundings." "No more excellent work is being done by our County Councils than the establishment of school gardens at selected centres to be cultivated in plots by boys of thirteen years of age and upwards under a local instructor; the encouragement of cottage gardening and allotments by the lectures of qualified persons, by prizes awarded to successful culture, and by the organisation, as at Maidstone, of schools of cookery."

— **FOOD OF PLANTS.**—The food of plants which is derived from the soil must be soluble either in water or such weak acids as are excreted by root hairs.—*D.*

— **RHODODENDRON GRIFFITHIANUM.**—This species ranks high in a genus which is remarkable for the large number of gorgeous-flowered species it contains. In the temperate house at Kew a large plant is now to be seen in full flower. The blossoms are produced in loose spreading trusses, averaging nine flowers to each truss. They are white, with a touch of pink on the outside, 5 inches across by 4 in depth. When not in flower, the size of the deep green foliage makes it a striking plant, the leaves often being 9 inches or more long, by 3 inches wide. In some gardens it is met with under the name of *R. Aucklandi*, and it is figured in "*Rhod. of the Sikkim Himalayas*," t. ii., under that name. For a large cool house few plants, if any, are more striking than this and other Himalayan *Rhododendrons*. Among other species and varieties flowering in the temperate house at Kew are *R. arboreum*, *Nuttalli*, *ciliatum*, *kewense*, *Edgeworthi*.—*D. K.*

— **SPINACH BEET.**—As a substitute for the ordinary Spinach this is very useful. Usually in dry summers there is a difficulty in keeping up a supply of Spinach, for the summer varieties are prone to run to seed quickly, and it is not always easy even to get the seed to germinate unless special attention can be paid to watering. In severe winters, too, Spinach is brought to a standstill, and the supply cut off for a time. The Spinach Beet variety is quicker in responding to a genial change of weather than the common Spinach, hence its value. In some places it is not accepted in the kitchen at all, in others only when no other is available. The present is a very good time to sow seed for securing a supply lasting until April in next year, one sowing from this date sufficing. Ground lately occupied with winter greens or Broccoli, lightly manured and dug deeply, will grow as luxuriant a crop as anything the gardener has to produce, it seemingly having no insect enemies. A light sprinkling of salt at the time of sowing or later is beneficial on light soils.—*W. S., Wilts.*

— **RHODODENDRON THOMSONI.**—Sir J. D. Hooker speaks in high terms of the beauty of this species—in the description accompanying fig. 12 in "*Rhododendrons of the Sikkim Himalayas*"—as he found it growing at an elevation of from 10 to 13,000 feet. At the present time several plants are to be seen in flower in the *Rhododendron* dell at Kew, where they form conspicuous objects among their surrounding neighbours. The flowers vary a little in size and shape, the average size being 2 inches long by 2½ across the mouth. They are produced in loose heads of eight or ten together, and are very richly coloured, being deep blood red, with a glossy or waxy surface. It has been used for hybridising, and several very good varieties are the result; the chief difference between these hybrids and ordinary garden varieties being in the looser heads, more tubular flowers, and the thicker or more waxy texture of the blossoms. In gardens where *Rhododendrons* are made a feature, as many species as are hardy enough for the district should be grown, as with very few exceptions they are showy and interesting.—*D.*

— **THE HORTICULTURAL CLUB.**—The Hotel Windsor was upon last Tuesday evening the scene of quite an exceptional gathering of the members of the Horticultural Club. All were present, saving only those who were unavoidably prevented by illness or absence from home. The occasion was the celebration of the eightieth birthday of the Secretary and founder, the Rev. H. H. D'Ombrian. After having given the usual loyal toasts, Sir John Llewellyn, Bart., rose and proposed the toast of the evening. He alluded in feeling terms to the great age and long service to horticulture of the Secretary. No one, he said, ever found fault with a clergyman for cultivating the hobby of horticulture. It was a refining pursuit, in every way consistent with his humanising calling, and tended to brighten the lot of those within his *cure*. Money, he said, was not everything, but it was in many cases an evidence of active esteem, and all the members had therefore united in contributing each an equal sum for a birthday gift. This was enclosed in a purse expressly worked for the Secretary by a lady, and which he had unfeigned pleasure in presenting to Mr. D'Ombrian. Mr. D'Ombrian in replying was visibly moved. He said that he recognised with pride the unexampled gathering. He saw before him many faces he had known for more than thirty years, and if there were some old faces missing, their places were now worthily occupied by those of their descendants. He lived in two worlds, his pastoral and his horticultural, but between the two he obtained nothing but refreshment. While not anticipating an indefinite future, he still hoped that he might be spared to celebrate many happy meetings with those he was addressing. Mr. Monro having spoken with satisfaction of the lightness of his labours in canvassing the members, and of the unanimity and alacrity of their replies, the company proceeded to an informal entertainment for the remainder of the evening.

DIPLADENIAS AND THEIR CULTURE.

(Concluded from page 385.)

WATERING.

NEVER water Dipladenias until the soil gets somewhat dry. They do not need heavy supplies at any time, yet when growing a due amount at each watering to moisten the soil through to the drainage. During the winter they must be kept moderately dry at the roots, but the "dry as dust" system hardly answers. Water must be given very carefully at starting, root action only needing moderate moisture, and when in free growth afford supplies as necessary, more being required when the flowers are developing. After flowering, or during the latter part of September and in October, merely afford sufficient to keep the leaves fresh, and gradually reduce the amount, very little being needed after that month and up to February.

TEMPERATURE AND LIGHT.

Dipladenias are hothouse plants. It is useless to attempt to grow them in an intermediate house or cool stove. Even in winter they require warmth—60° to 65° at night, and from starting in the early spring 70° to 75° should be the minimum by night and in the daytime in all but very dull weather and on severe frosty nights. Relatively low night temperatures, however, do no harm, provided the days are bright and the heat mounts up to 85° or 90°, or more. This temperature they enjoy from sun heat, and that they mostly get in stoves from April to September inclusive.

Rough and frosted plate glass roofs do not suit Dipladenias, and though a slight "summer cloud" shading does no harm after flowering begins, the less of it the better, aiming more at a diffusion than obstruction of the sun's rays. They must have light to flower freely, making stout, short-jointed, hard wood. After August the more glare of sun the better, for the main growths cannot be too thoroughly ripened; even trellis plants are better loosened from the conical or globular shapes, and the shoots spread out to the late summer and autumn sun. It enables the plants to store matter for the succeeding year's growth, and by this procedure a good start will be secured.

PRUNING.

The flowers are produced on the young wood of the current year, and in most profusion at the latter part of the summer. Overcrowding is a great evil, therefore train so that every shoot has its fair share of light, rubbing off weakly growths, for they do nothing but rob the vigorous and deprive them of both nourishment and light. Stopping must not be practised, except for special purposes, but keep the growths sturdy by plenty of space and full exposure. After flowering, thin out the wood well, cutting away nearly all that of the current year to let the sun into the plants. In the late winter or early spring, say February, cut back the main shoots to a few buds, spurring them in like Vines, always making a reservation of main shoots required for covering the trellis, and these hard and ripe in the wood.

STARTING.

Let the plants move before attempting any disturbance of the roots, then turn them out of the pots, remove as much of the old soil as desirable, reducing the ball about half, and repot, pressing the soil moderately. Water very carefully, and sprinkle the plants occasionally. This will bring them on better than waterings at the roots, but when they get hold of the new soil they will need more copious supplies. Avoid, however, making the soil wet, either by sprinkling or watering too much. Young plants may be given a shift in the early summer, but avoid overpotting at any time, though a rather large size of pot will be required for large trellis plants. In repotting these be careful to remove the loose soil only, as the plants are rather impatient of much root interference, yet give some soil annually, and always see that the drainage is perfect.

The plants appreciate frequent syringings, provided they are given in the early part of fine afternoons, never excessively, and not so that the water will hang on the foliage for a considerable time. The syringing must not be practised over the flowers, but damping in the morning and early afternoon proves advantageous. In the early spring and summer months a brisk moist heat is necessary to bring the plants along; they enjoy moisture better when arising from a large extent of damped surface than a deluging of the growth.

Dipladenias require a fair share of air, not a great amount at one time and none at another, but some each day of their growth, to insure a change of atmosphere. The early opening and the early closing system suits Dipladenias to perfection, the bottled up sun heat doing much more good than the stuffy heat from hot-water pipes.

PESTS.

Mealy bug likes Dipladenias, but there is no need to have it if the house be vapourised with nicotine. This also acts well against scale, as the young are just as easily killed as green fly. Thrips and red spider also like these plants; but they cannot make great headway

where due attention is paid to adequate supplies of moisture and judicious syringings. Vapourisation with nicotine kills thrips, only practise it often enough, and red spider does not like it. By those means the pests can be kept under, and they must, for unless the plants are kept clean and healthy they cannot be expected to thrive. Winter dressings are useful, and touching up parts infested with mealy bug and scale with methylated spirit, applying by means of a small brush, are not overwhelming processes, and these little timely attentions give plants much of their after beauty, as they flower in measure of their cleanliness, and are appreciated accordingly.

SPECIES OR VARIETIES.

D. amabilis.—Leaves oblong-acute, shortly stalked. Flowers rosy or purplish crimson, 4 to 5 inches in diameter; petals round and stiff, borne in clusters from May to October. A hybrid between *D. crassinode* and *D. splendens*.

D. amena.—Leaves oblong-acuminate. Flowers pink, suffused with rose; petals round, stiff, and not reflexed. Free blooming, and better than *D. splendens*, which it somewhat resembles, occasionally being as pale in colour. A garden hybrid, with exceptionally good foliage.

D. boliviensis.—Leaves oblong-acuminate. Flowers white, with a golden yellow throat, about 2 inches across, borne in sub-terminal or axillary racemes of three or four; stems slender. A pretty, small-growing species. Bolivia, 1866.

D. Brearleyana.—Leaves opposite, oblong, acute, dark green. Flowers (opening pink) rich crimson, very large, freely produced from May to October, and borne well above the foliage. One of the finest varieties. Garden hybrid.

D. crassinode.—Leaves oblong lanceolate. Flowers rose coloured, unapproached for loveliness of shade, but superseded by the hybrids. Rio Janeiro.

D. hybrida.—Leaves large, stout, bright green. Flowers flaming crimson red, freely produced; very beautiful. Garden hybrid.

D. insignis.—Leaves or foliage very strong and growth stout. Flowers rosy purple, striking. Garden hybrid.

D. Lady Louisa Egerton.—Leaves long and lanceolate, rough and leathery. Flowers white, suffused with pink, eye rayed with a deeper shade, round, of great substance, and 6 inches or more in diameter. Garden hybrid.

D. nobilis.—Free growing. Flowers orange red to rosy purple, large, handsome. Garden variety.

D. Regina.—Growth neat, early flowering. Flowers blush at first changing to flesh colour, with rose suffused on throat. Garden hybrid.

D. rosacea.—Flowers rosy pink, suffused and bordered with a deeper shade; throat yellow, with a rose ring at the mouth. Garden variety.

D. (Echites) splendens.—Flowers white, suffused with pink, produced on spikes successively for months. Foliage broad, and shoots stout. Organ Mountains.

D. s. profusa.—Leaves oblong-acuminate. Flowers (fig. 77) carmine, 5 inches in diameter, and borne in bunches from the axils of the leaves. Garden hybrid.

D. s. Williamsi.—Flowers similar to the species, but with a deep pink throat; free flowering and a great improvement on the species. Garden variety.

D. Thomas Speed.—Flowers large; petals broad, round and of great substance, rich rosy crimson, rayed blush white, with a golden eye flaked with red. Growth free and floriferous.—G. ABBEY.

VEGETABLES FOR HOME AND EXHIBITION.

SEAKALE.

A GARDEN without Seakale would be deficient in a most important crop. Important in many ways—the chief one being that it is a vegetable that supplies a welcome and radical change to the menu. It is the forerunner of a new order of things, and the advent of Seakale in the kitchen paves the way for a line of varied produce continuing through the summer, and none is more appreciated than the first dish of tender forced Seakale. The date of this depends largely on the facilities for forcing, and the supply of roots suitable for the purpose. The demand for forced Seakale varies likewise. This winter there has been no lack of vegetables, for which the mildness of the season is accountable. During severe winters, however, the demand for Seakale exceeds the supply.

There are various ways adopted for forcing this useful product; but, in the first place, let us glance at the culture of it. Average garden soil is suitable for Seakale, and good manure from the farmyard suits it admirably. Frequently one sees the Kale bed in an out-of-the-way shaded corner of the garden, so placed that it may be easily protected prior to forcing; but it is far better to grow it fully exposed to the sunshine. A commencement must be made either by propagating

from seeds or planting matured roots. The latter course is advised, as a saving of time and labour; but if the former is adopted, seeds may be sown in April, in drills about a foot apart, and when the roots have attained a fairly good size, they are all the better for transplanting. The drawback to raising Kale from seed is that a year must be sacrificed,

will be necessary to thoroughly prepare the ground, as Seakale is, more or less, a permanent crop. If the subsoil is good the ground may be trenched a couple of spits deep, with good manure worked in the bottom and between the spits. Methods of planting must be ruled by the intended means of forcing. Supposing the Kale is to be

FIG. 77.—*DIPLADENIA SPLENDENS PROFUSA*.

which is not necessary when growing from roots. It is advisable, whether transplanting or leaving the Kale to mature where it is sown, to allow ample room between the roots, by which the crowns will be benefited.

Before planting roots, which operation may be performed in favourable weather any time between the late autumn and spring, it

blanched on the ground, then there must be room left for getting between and round the crowns, especially as the plants when established cover a wide area. Square beds about 4 yards each way, with a pathway round, are convenient, and will accommodate three rows of plants at even distances. The advantage of planting in square beds is that leaves and other heating material used for blanching may

be utilised to greater advantage, and if necessary be removed from one square to another in the event of succession. It is advisable to cut off the prominent buds on each crown before planting, as they will throw flower stems. The roots should be covered with 2 or 3 inches of soil, and be trodden in firmly as the operation proceeds, and for the first season a salad or other shallow-rooting crop may be grown between the crowns.

Free use of the hoe is necessary during the summer, and in dry weather an occasional feeding with liquid manure will assist in the building up of the crowns. As the foliage decays it should be removed, and the surface soil be lightly forked over, finishing off with a mulching of good manure. The crowns are now practically exposed, and, no matter what is the proposed method of forcing, some means of protection during severe weather is advisable. Rough straw from the stable, or leaves, or a mixture of the two, will be suitable for the purpose if heaped over the roots not otherwise protected by pots. We will suppose that the Kale is to be blanched on the ground, and forced so far as means will allow. Seakale pots with moveable tops are the readiest means of protection and blanching, but in their absence large drain-pipes, flower pots, and tubs are used. Any such should be placed over the crowns, and the whole covered with litter, and the result will be early growth of superior quality. The arrangements may be such that the Kale comes in successionally, and the period of cutting is lengthened, and this is always preferable to having a quantity in at once and then a dearth.

Supposing pots are placed over a portion of the crowns, the remainder having only the protection of leaves. Fermenting material, in the shape of littersy stable manure, may be heaped round the pots, and this will assist in forcing the growth. As the Kale is cut the pots may be removed further along, and the process of covering be continued. Though naturally later, Seakale blanched in this way on the ground is superior in quality than when subjected to hard forcing indoors. When the crop is completed remove the leaves and litter from the ground and apply a dressing of manure, which should be dug in round the plants. A number of growths will be emitted from below where the Kale was cut, and if all are left several weak shoots are the result. To obviate this the buds should be thinned to two or three of the best, which will be the crowns for the future.

For early supplies and quick forcing the Mushroom house is the favoured resort, than which there is no better place, as there are both the necessary heat for pushing growth and the darkness for blanching. The best flavoured Seakale, however, is that which is forced gently, as when grown in a high temperature the growth is thin and weakly, beside being destitute of flavour. No Seakale is equal to that grown without artificial heat, therefore the more gentle the forcing process the nearer perfection will be the produce. Decayed leaf mould, spent manure, or old potting soil are suitable for surrounding the roots, the crowns of which should be left exposed. One good watering is generally sufficient, after which the natural moisture of the Mushroom house dispenses with further supplies of liquid. Where Mushroom houses are not available any place of suitable temperature will answer the purpose, provided light is entirely excluded. Roots taken up and forced are of little use afterwards, and may be dispensed with, but forcing on the ground as suggested above may go on for an unlimited period. The best Seakale for table is stout, fleshy, and fresh. Slowly forced Kale is more likely to possess these characteristics than when subjected to excessive heat, though when it is desired to get it as early as possible hard forcing must be resorted to. In such cases Kale should be cut and sent direct to the kitchen, in order to preserve the crispness, which changes to flabbiness if allowed to lie long after cutting.—GROWER AND JUDGE.

POLYANTHUSES.—I was so much disappointed with the rough coarse aspect of the border Polyanthuses staged at the Drill Hall on the 26th, that I gladly accepted an invite from Mr. S. Mortimer to run down and see his breadth of these beautiful spring flowers again, as I did last year. To one who appreciates these Polyanthuses beyond all other spring flowers, it was a treat to look upon what is, I think, one of the finest collections in the kingdom. Most of the plants are three years old, and many of them are from 15 to 18 inches across, truly wonderful clumps! There were altogether some 1800 or 2000, perhaps more; planted thinly on the sandy soil of Rowledge, where they thrive luxuriantly. I noticed that about 2000 seedlings from an autumn sowing had already been put out for next season's flowering. That is the way to treat these plants. Sow seed thinly in August, let the plants remain in the bed all the winter, and plant out in the middle of April where to bloom. They then get well rooted ere warm weather sets in, and make very fine clumps by next winter. Plants from spring sowings are seldom ready to put out before June, when the weather is often hot and dry. The strain is very fine and varied. Colours vary exceedingly, and are indescribable; but the quality found in the flowers is of the best, far surpassing what is so commonly seen. There is so much room for improvement in common stocks, and so many as we see in gardens and in the markets are so poor in colour and quality, that such a fine strain as I have referred to can hardly be overpraised.—A. D.

KENT COUNTY CHRYSANTHEMUM SHOW.

THIS show, which is annually held in the Rink, near Blackheath Station, is looked upon by many as an index, so far as quality is concerned, of the flowers that are to be shown. Each year a charming display is brought together, cut blooms, both of Japanese and incurved, being invariably of good quality. The eleventh annual exhibition will be held on Wednesday and Thursday, November 2nd and 3rd, 1898, and it is hoped that the status of the Society will be well maintained. Schedules, in which some excellent prizes are offered, are now ready, and may be obtained from the energetic Honorary Secretary, Mr. F. Fox, The Cedars Gardens, Lee, Kent.

SPRING NOTES.

THE French N.C.S., although a young society compared with its English prototype, shows signs of increasing vigour and prosperity. Its journal is a valuable means of disseminating information among those members who live at a distance from the seat of operations, and the last number issued shows that there are now 419 members. The next Conference will be held at Troges on the 5th November.

On the occasion of the Conference at Orleans last November several interesting papers were read, the principal of which have recently been issued in separate form by Mr. O. Doin, publisher, Paris, in a convenient pamphlet of about thirty-six pages. Illustrations accompany these articles, which deal with the following subjects:—"Maladies and Parasites of the Chrysanthemum," by Mons. Chifflet; "The Fertilisation of the Chrysanthemum," by Mons. Gerard; and "The Best Manures and Composts to Use in Chrysanthemum Cultivation," by Mons. H. Fatzer.

The literary work accomplished by some of these Continental Chrysanthemum societies is worthy of remark. Last November the first exhibition of the Amsterdam Chrysanthemum Club was held, and an official catalogue compiled for the use of visitors at a small charge. Mr. J. K. Budde wrote for this work a sketch of the history of the Chrysanthemum, which was followed by a paper on "Cultivation;" the rules of the Club next appear, together with a list of exhibitors, the whole forming a neatly printed pamphlet of fifty-six pages.

The foreign catalogues of novelties are now all to hand, and form, as usual, a goodly pile. The best of all in style is that issued by Mons. Ernest Calvat, who supplies a large double-page phototype illustration of one of his novelties, President Bevan, and a chromo-lithograph of a deep yellow coloured Jap called General Paquie. Mons. Calvat's 1898 novelties comprise thirty-two varieties, which have been awarded seventy-seven first-class certificates or awards of merit. Other competitors for public favour are Messrs. Chantrier, Allemand, de Reydellet, Rozain, Charment, Nonin, Morières, Heraud, Délaux, Lacroix, Bruant, and several others less well known.

A special circular of Italian novelties from Mr. Scalarandis, gardener to the King of Italy, also reminds us of that gentleman's efforts as a recent raiser. Most of his new seedlings have been shown at the leading Continental shows, and appear to be more highly thought of there than they were here when he exhibited a collection at the N.C.S. Jubilee Show in 1896. At Brussels during the past season Mr. Scalarandis was appointed Knight of the Order of the Crown of Belgium, and other distinctions appear to be awaiting him. The movement in Chrysanthemum culture seems to be spreading in Italy, although none of the raisers there seems to have obtained anything that appeals specially to English taste. A few weeks ago an eminent amateur in the north of Italy sent me a large number of photographs for inspection, all newly raised Italian seedlings, but the really promising sorts were certainly in the minority. Judging by the appearance of them they were weakly grown and the centres badly filled.

It is, however, agreeable to be able to record that the Italian growers seem to be in earnest. A circular has just reached me announcing the formation of what they call "La Società Nazionale Italiana di Chrysanthemisti." The Society draws attention to the existence of national societies in England and France, and a provisional committee has been formed to carry out the formation of a society on similar lines so soon as a sufficient number of applications has been received. Amongst others the names of our friend Mr. Briscoe-Ironside and Mr. Scalarandis appear, the latter as President. The headquarters of the Italian N.C.S. are to be at Milan, and the Secretary, Mr. Paolo Radaelli, is a well-known nurseryman and Chrysanthemum grower there.

Although the chances of duplicate names amongst the Continental novelties are somewhat reduced by the action of the French N.C.S. requiring registration, there are still some of the new names that may cause a little confusion by their resemblance to others already in existence, and others are open to the objection of great length, such, for instance, as

Madame la Douavrière Lampsius van den Velden, Souvenir de l'Exposition du Havre, Avenir de la S.C.D.N., which being fully expressed is Avenir de la Société des Chrysanthémistes du Nord.

From America there is not much to chronicle at present. Mr. T. H. Spaulding's familiar little square catalogue bears a new name, that of George Atkinson as his successor. Mr. Atkinson, it appears, has acted as Mr. Spaulding's manager for the past ten years, and therefore, no doubt, fully knows what is expected of the Chrysanthemum in America and elsewhere. After perusing Continental catalogues it is always refreshing to turn to the American ones. There is a crispness about American nomenclature that cannot fail to be appreciated, and the 1898 American novelties illustrate this fact once more. Avoiding personal names, which will always appear in every raiser's catalogue, Spottswood, Snow Queen, Merry Christmas, Autumn Glory, Boundless Snow, Black Hawk, Quito, and the like may be cited as illustrations.—C. HARMAN PAYNE.

HARDENING BEDDING PLANTS.

ABOUT the end of May or the first week in June is usually a safe and convenient time to begin the important work of bedding out. Two great essentials to success in the matter are to have good plants, and by exposing them freely to all weathers, short of actual frost, to bring them into such a condition by bedding-out time that they may grow with as little check as possible after being planted out. Where plenty of pit room is at command Pelargoniums will have been placed in them during April, and will now only need the lights to be placed on at night whenever there is the slightest danger of frost occurring, or when cold cutting winds prevail.

In nearly all gardens there seems at this time of the year to be a scarcity of cold pits and frames, but it is an easy matter to quickly form rough ones with a few boards, and old lights to cover them, or failing the latter, cross stakes and canvas answer admirably for purposes of protection. Warm positions in front of walls and fences can also be utilised for many of the less tender plants, such as Ivy-leaved Pelargoniums and Lobelias, but even in their case it is necessary to have some means of protection at hand should a sudden frost occur. Some gardeners, I think, make a great mistake in their anxiety to get their whole stock of bedding plants hardened at once, when by following some other course they might often gain a great advantage. Let this serve as an example. If the earliest and best plants are selected for hardening first, the weaker ones will be much benefited by remaining a couple of weeks longer in heat, and as the weather is by that time usually more settled, a week or ten days' exposure in pits renders the plants quite fit for planting out.

It is surprising how much may often be gained by the exercise of a little ingenuity of this description, for attempting to harden a plant before it has been grown to the required size often causes the flower gardener to "run short" of material. As the houses are gradually cleared of Pelargoniums, the space can be utilised for Alternantheras and other tender bedders, which if placed in cold pits ten days before they are wanted for planting out will, if rightly treated, be properly hardened. I have seen tender plants of this description placed in cold pits weeks before they were wanted for bedding out, and when planted by the side of others started much later, and only removed from warm houses a fortnight before being planted in the flower garden, they were a comparative failure, having got into a stunted condition through being placed in cold pits too early. I have always found that with such tender bedders the hardening should be done quickly. Get the plants strong and vigorous before they leave the houses, choose warm weather for transferring them to pits, admit air judiciously for a few days, after that increase the amount each day till full exposure can be safely given, then the results are sure to be satisfactory.

It is a pity that the great value of planting Calceolarias early is not more generally practised, for well hardened plants may be now safely planted out in any part of Britain. I planted some in a very exposed position a fortnight ago, and although we have had 6° of frost since, they are quite uninjured. Early planting enables them to withstand the drought of summer, and to flower grandly throughout the season. If those who fail in getting these showy plants to thrive satisfactorily during the summer would only try early planting, I feel sure they would succeed; but it is of course necessary to plant sturdy specimens which have been fully exposed night and day for the last two weeks.—FLOWER GARDENER.

THE month of May is one of the busiest periods of the year. Thousands of bedding plants during this period requiring special attention, the gardener must be up and doing, so that the wants of each and all may be promptly supplied. Softwooded plants which have been propagated from cuttings inserted in autumn, and potted singly in small pots or spaced out in boxes during March and April, demand now cold frame treatment. If Lobelias or bedding Pelargoniums are allowed to stay in heat when the plants have attained to profitable size they must of necessity become drawn and weakened. This is especially so if to the heat is added shade, which is now becoming dense even in late vineries, where large quantities of bedding plants are often located.

A bed of ashes in a cold frame should be prepared for standing the plants upon, as it is essential that a cool, damp base be provided. The frames must be sufficiently deep to allow of the largest plants receiving

the protection of a glass light both throughout the day and night at first and on specially unfavourable occasions afterwards. If the stems of the plants have become soft, and the leaves thin in texture through remaining beyond their proper time in heat, lessened light, and a moist atmosphere, the too sudden exposure to the outside atmosphere for a length of time will cause the foliage to be discoloured. The growth of the plants will also be checked to a more or less injurious extent. The plants ought to have as much space to stand upon as can be afforded, the plan of placing them close enough to touch each other being usually the best. Further space can be given later if necessary. In a fully exposed frame the light is abundant, and helps materially in hardening the cuticle of the leaves and stems. Arrange the plants so that water may be readily supplied to them.

The watering of bedding plants in frames consumes a large amount of time if the soil in the pots cannot be easily seen. It is much better to water carefully than at haphazard, because some will receive water that may not require it then, while others that do may be overlooked. In sunny, breezy weather, it is not too often to look over the plants twice in the day, morning and evening, and if essential, at noon too.

For the first few days after placing the plants in the frames keep the lights on fairly close, shutting up early so that a good heat may be retained, approximating somewhat to the temperature they may have left. Should the nights be cold cover the lights with mats, but remove these early in the morning. Give air carefully according to the weather, and on calm, warm days, lift off the lights altogether, but replace in the afternoon, though ventilation may be left on until evening. This treatment will gradually and thoroughly inure the plants until they can withstand all but cold, stormy weather, in the day, and frosty nights. After the 24th of May it is safe to expose fully all gradually hardened plants, frosts at nights having, except in very unfavourable positions, ceased to be dangerous.

Frames, after the date above mentioned, then come in handy for the hardening treatment of the really tender bedding plants used in carpet bedding, including Coleuses, Alternantheras, and Mesembryanthemums. They likewise serve to finish off Begonias, Petunias, Iresines, Ageratums, Carnations, and others, also for the pricking out and strengthening of Golden Feather, which does not need such early raising and pricking out which is often accorded to it.

Earlier in the month the strengthening and hardening of all half-hardy annuals should be dealt with, for by the time the frosts are past full exposure may be accorded to them, and they will be all the stronger, as well as better rooted, for the final planting out at the end of the month.—E. D. S.

AUTUMN VERSUS SPRING DIGGING.

It has been well established by scientific experiments and investigations that a considerable loss of the valuable nitrates formed in soils during the summer months takes place during the winter if the ground be unoccupied by a crop. If the soil is loose—i.e., recently stirred or dug—the loss is still greater, for while cultivation in the spring and summer increases the formation of nitrates the reverse is the case when the soil is cold and wet. Theoretically and practically, it is therefore desirable to have all ground occupied with crops of some kind during winter, even if they have to be dug into the soil in the spring to make room for special crops.

This is a little elementary science which may concern beginners to understand, and it is only mentioned here to illustrate the point to be referred to presently. The fact is, there are practical considerations which must influence the time chosen for many gardening operations, and the most important of these are the weather conditions prevailing at the time they are undertaken. In sowing, planting, and digging, whether we are to obtain the best results or not often depends entirely upon the state of the soil, and especially so in the two last-named operations.

There is another matter which must be remembered—namely, labour can often be more conveniently spared in the autumn than in the spring, so that in weighing the respective advantages of the two systems many things require to be kept in view. It is occasionally laid down as a rule admitting no exception that ground must be either cropped in autumn to stand the winter, or digging must be deferred to spring, if soil exhaustion is to be avoided. Like many hard and fast rules, this is open to serious objections, and I will describe one which may not be scientific, but it has a commercial bearing that can be fully appreciated by all who are engaged upon the problem of securing the best possible returns from the least expenditure.

Having in my occupation a large extent of land that is worked almost entirely by manual labour, the autumn and winter enabled me to have a large part of this dug under very favourable conditions. About 2 acres had, however, for several reasons, to be left until the spring, and then we were unable to wait for the rain which has come at last; and the work in consequence had to be performed with the soil in a dry, hard, and most unpromising state. With regard to some soils the dryness would be an advantage, but mine is peculiarly heavy and difficult land, as it is absolutely unworkable when wet, and when dry it is almost like bricks, and scarcely breakable. Still it had to be done, and the result was as follows, judged by the cost alone, though the work was less efficiently executed into the bargain. The autumn digging cost between £3 and £4 per acre, the average being nearly the last-named sum; but our spring work, performed with forks, has cost nearly £6 per acre, and the results were practically identical by piece or day work, and tested with different gangs of men.

Whether the average value of the nitrates washed out of the soil during winter has been determined I do not know—it would, of course, vary greatly according to the mechanical and chemical constitution of the land; but now fertilisers are so moderate in price, it is difficult to see what is gained by the increased expenditure under such circumstances as these detailed here. An additional cost of £2 per acre is a serious item, and though this would not be the same in all cases, yet I know many who have to deal with a similar soil to mine, and who presumably might expect a similar experience.

The benefit arising from having ground cropped during the winter is unquestionable, but as there are few who pay heavy rents near towns, and who have to make a living from the land, that can afford to leave any of it unoccupied for several months at a time, this point does not need to be impressed upon them, nor can many gardeners avoid cropping their ground to the fullest extent; but it sometimes happens that provision has to be made for later crops, or from pressure of other work, something has to be placed on one side. It is, however, a subject for consideration that an actual material saving in expenditure can be effected under some circumstances by autumn digging as opposed to similar work in spring.—A MARKET GROWER.

ODONTOGLOSSUM PESCATOREI DUCHESS OF WESTMINSTER.

THERE are many varieties of *Odontoglossum Pescatorei* extant at the present moment, several of which are very beautiful. There is, however, still room for more, as was proved at the Drill Hall on the 26th ult., when Mr. N. F. Barnes, gardener to the Duke of Westminster, Eaton Hall, Chester, showed *O. P. Duchess of Westminster* (fig. 78, page 413). This form is very handsome, and was the subject of much admiration, and received an award of merit from the Orchid Committee of the Royal Horticultural Society. The shapely flowers are rather over the average size, and are of exceptional substance. The spots on the white ground are of a rich rosy maroon, and are very abundant. The variety is one of the most distinct that has been exhibited.

ODONTOGLOSSUM NÆVIUM MAJUS.

THIS is one of the most beautiful of *Odontoglossums*, the blossom being pure white, closely covered with small blotches of crimson. Although not a difficult plant to grow, it requires care, and should be in a position where it can be closely shaded during the summer months, and where plenty of fresh air will play freely over the foliage. It is not a vigorous rooting plant, and does best in small pans suspended from the roof in the coolest house. Fill these half way up with clear crocks, and use for compost equal parts of peat and moss. Water freely during the summer, and in winter sufficiently to keep the bulbs from shrivelling.

CYMBIDIUM LOWIANUM.

We have a good plant of this species in a 10-inch pot carrying seven spikes, and these are large and contain a number of flowers. I grow this plant in a cool fernery, and the specimen in question is elevated so that one has to look up to the flowers. The spikes are not tied at all, but spread naturally, those now in flower covering an area of nearly 8 feet across. *C. giganteum* is grown the same way, and the difference between plants so grown and others tightly tied up is so marked that tying should never be practised except when room is scarce.

EPIDENDRUMS.

Many of the tall-growing section of *Epidendrums* are now flowering, and are extremely pretty, their one fault being the fact that amateurs with small houses have not the room to grow them. But there are positions even in small houses where the plants may be accommodated. In a cool intermediate house lately I noticed one or two species flowering profusely, trained up under the roof glass, and I can safely recommend those who are short of room to try this plan. The roots of most of these kinds are fairly strong, and like a large pot and rough open compost, plenty of moisture all the year round, and careful attention in the way of keeping down insects.

The deep golden yellow balls of flowers produced by *E. xanthinum* are very beautiful, and show well in company with those of the somewhat weaker *E. radicans*. These are extremely bright and pretty, the scarlet and yellow making a fine contrast. *E. Wallisi* again is a very beautiful species, nearly always in flower, and one of the easiest of all to grow. The flowers are of various shades of yellow and purple, produced two or three together on the top or near the top of the growths. Other good forms in this way are *E. syringothyrsus*, *E. ibaguense*, and the fine hybrid *E. O'Brienianum*.—H. R. R.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—MAY 10TH.

THE display at the Drill Hall on Tuesday last was a comparatively small one, the exhibitors being much less numerous than has become the rule of late. The exhibits for the adjudication of the Floral Committee were bright and interesting, while the few Orchids that were staged were of good average quality. Fruits and vegetables were not by any means abundant. The fact that the Temple Show will be held on the 25th inst. doubtless accounted for some absentees.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with Messrs. G. Bunyard, J. Cheal, J. H. Veitch, G. W. Cummins, M. Gleeson, A. H. Pearson, F. J. Saltmarsh, A. Dean, W. Bates, W. Farr, G. Woodward, G. Wythes, G. Miles, F. Q. Lane, W. Balderson, J. Smith, G. Reynolds, G. Norman, R. Fife, and A. Poupart.

Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, showed half a dozen dishes of French Beans grown from seed sown on March 28th. The best variety was Wythes' Imperial Mohawk and Ne Plus Ultra. Mr. Wythes also sent a seedling Lettuce, a Cabbage variety of promise, to be tried at Chiswick, and received a vote of thanks. Mr. W. L. Bastin, gardener to A. Henderson, Esq., Buscot Park, Faringdon, sent two dishes of Strawberry Royal Sovereign. The fruits were of medium size and good shape. Mr. Bastin also sent Melon Buscot Park Hybrid, but it was passed (vote of thanks).

Mr. G. Norman, gardener to the Marquis of Salisbury, Hatfield, exhibited three boxes of Strawberry Royal Sovereign that were probably the finest specimens of the variety that have ever been exhibited. They were of immense size and splendid colour (silver Knightian medal). Mr. W. Taylor, gardener to C. Bayer, Esq., Forest Hill, sent Peach Waterloo from a pot tree (vote of thanks); while Mr. J. Ryder, gardener to the Dowager Countess of Limerick, St. Albans, sent two dishes of Peach Alexander (cultural commendation). Mr. J. Hudson, Gunnersbury House, showed fruits of Cardinal Nectarine from pot trees started on December 2nd. They were of good quality (cultural commendation).

A collection of Radishes was staged from Chiswick that represented various stocks sent for trial by Messrs. Barr & Son, Sutton & Sons, Toogood & Son, Watkins & Simpsons, of which Wood's Frame from the latter firm, Sutton's Forcing White and Red from Messrs. Sutton & Sons, and First of All White and Red from Messrs. Barr & Sons, received awards of merit.

PRIZES FOR FLAVOUR.—The first prize for a dish of Apples was awarded to Mr. R. Bullock, gardener to C. P. Serocold, Esq., Maidenhead, who showed Herefordshire Pearmain; Mr. G. Woodward, Barham Court, taking second place with Calville Rouge. The second prize only was given for Pears, and this to Mr. C. Herrin, Dropmore, for Beurre Bretonneau.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. C. T. Druery, O. Thomas, J. Fraser, R. Dean, G. Stevens, W. Howe, J. Hudson, J. Jennings, T. Peed, H. B. May, J. Fraser (Kew), G. Gordon, J. D. Pawle, C. E. Pearson, C. Jeffries, C. E. Shea, H. J. Cutbush, E. T. Cook, D. B. Crane, T. W. Sanders, H. Turner, C. Blick, C. E. Cant, E. Mawley, and J. Walker.

Messrs. J. Veitch & Sons, Ltd., Chelsea, sent a number of baskets of hardy plants and shrubs, including *Anemone nemorosa alba plena*, *Daphne cneorum major*, *Hydrangea japonica Mariesi*, *H. japonica flore rosea*, *Aubrietia Souvenir de William Ingram*, *Citrus trifoliata*, *Notospartium australis*, *Cytisus Schipkænsis*, *Rubus deliciosus*, and *Sambucus racemosa serratifolia foliis aureis*. The group of miscellaneous flowering and foliage plants from Messrs. W. Cutbush & Sons, Highgate, was varied and handsome. Amongst the most conspicuous were *Erica ventricosa coccinea minor*, *E. v. magnifica*, *E. Cavendishi*, *E. perspicua nana*, varieties of *Azalea mollis*, *Boronia heterophylla*, *Hydrangea Thomas Hogg*, *Carnation Princess May*, *Azalea Vervaeana*, *Wistaria sinensis*, with Palms, Ferns, and others (silver Banksian medal).

The plants of *Azalea indica* from Mr. Charles Turner, Royal Nurseries, Slough, though small, were splendidly flowered, and comprised new varieties, particularly rich in colour. There were ten varieties in all—namely, *Marie Vervae*, *Mons. Chas. Vuylsteke*, *Madame Joseph Vervae*, *Louise Cuvelier*, *Ami Chas. Vermeire*, *President A. d'Heane*, *Ami Victor Cuvelier*, *President Van Imschoot*, and *Le Printemps*. Mr. Turner sent also *White Rambler Rose Thalia*, and *Malmaison Carnation Princess May* in splendid form. Messrs. W. Balchin & Sons, Hassocks, staged *Boronia heterophylla*, *B. serrulata*, *Erica perspicua nana*, and the bright blue *Browallia elata* in splendid form. Mr. D. Storrie, Glencarse, sent a collection of border Auriculas, amongst which the yellow forms were most conspicuous.

Messrs. F. Miller & Co., Fulham Road, S.W., sent crimson and white East Lothian Stocks, with Ferns and Golden Feather. Mr. H. B. May, Upper Edmonton, was represented by a collection of Crotons, including beautiful little specimens of many varieties. The colours were splendidly developed (silver Banksian medal). Hardy shrubs and alpine plants in variety were shown by Messrs. Paul & Son, Old Nurseries, Cheshunt. There were *Cerasus Wateri*, *C. avium fl.-pl.*, *C. myrobalana pendula*, *Kerria japonica*, *Cydonia Maulei*, *Ribes sanguineum*, *Pyrus albo plena*, *Iberis superba*, *Ribes aurea præcox*, *Phlox G. F. Wilson*, *P. stellularia*, *Primula Sieboldi Brilliant*, *Phlox atro-purpurea*, *Saxifraga Wallacei*, *Geum Heldreichi*, *Aubrietia tauricola*, and *Hutchinsia alpina* amongst others (silver Banksian medal).

Cut Roses from Mr. G. Mount, Canterbury, were in superb form. Those shown in the orthodox boxes, as well as others on long stout stems,

were alike rich in colour, of good shape and great substance. Particularly striking were Catherine Mermet, Ulrich Brunner, Mrs. John Laing, The Bride, Susanne Marie Rodocanachi, Général Jacqueminot, Niphetos, Madame Gabriel Luizet, Captain Hayward, and Marie Finger (silver Flora medal). Messrs. J. Cheal & Sons, Crawley, sent various flowers, in which Violas were in charming form, as were Pyrus, Brooms, Cerasus, Acers, Gorse, and many besides.

Two groups of Roses in pots were exhibited by Messrs. W. Paul and Son, Waltham Cross. The plants were healthy, and producing flowers of good quality. There were also numerous cut blooms in boxes. The varieties comprised La France, Duke of Teck, Enchantress, Duchess of Albany, Caroline Testout, Mdle. Eugène Verdier, Jeannie Dickson, Violette Bowyer, Victor Verdier, Danmark, Alphonse Soupert, Gustave Piganeau, Duke of Edinburgh, Gloire Lyonnaise, Madame Montet, Marchioness of Lorne, and Dr. Andry (silver Flora medal). Mr. A. Tulett, Crockenhill, Swanley, sent a good double scarlet Pelargonium named A. Tulett, and Mr. B. Bennett, Dunstable, showed a grand flower of *Dracæna indivisa*. Messrs. Paul & Son sent some Cannas in variety, and a good double yellow *Alyssum saxatile*.

A collection of Alpine Auriculas was arranged by Mr. J. Douglas, Great Bookham, Leatherhead. Several of the varieties were of high quality, notably Melpomene, Almira, Perfection, Captain, Ziza, Dean Hole, Apollo, Melaine, Lord Collingwood, Marie Corelli, Clytie, Firefly, John Gilbert. Mr. G. Stevens, Putney, was represented by a small collection of good Carnations.

The whole of one side of a long table was occupied by Messrs. Barr and Sons, King Street, Covent Garden, who showed miscellaneous hardy flowers and a beautiful collection of Darwin Tulips. Amongst the former were Violas, Primulas, Saxifragas, Orchises, Phloxes, Iberis, Anemones, Fritillarias, Irises, Scillas, and several others. The Tulips were very handsome, and included The Shah, Hecla, May Queen, Chas. Dickens, Aurora, Apricot, Glow, Queen of Roses, Dorothy, Phyllis, Joseph Chamberlain, The Sultan, and Early Dawn. There were also several Tulip species (silver-gilt Flora medal).

ORCHID COMMITTEE.—Present: H. Little, Esq. (in the chair); with Messrs. J. O'Brien, de Barri Crawshay, H. M. Pollett, J. T. Gabriel, W. H. Young, F. J. Thorne, H. J. Chapman, J. Jaques, E. Hill, T. W. Bond, W. Cobb, J. Douglas, T. Statter, H. Ballantine, W. H. Protheroe, and T. B. Haywood.

The group of Orchids from Messrs. J. Veitch & Sons, Ltd., Chelsea, was very handsome. The flowers were of splendid quality, and there was a fine assortment. Amongst the prominent ones were *Cattleyas intermedia alba*, *Schröderæ cœrulescens*, *Mendeli*, *Mossiae*, *intermedia*, and *Lawrenceana*, *Lælias purpurata* and *Latona*, *Lælio-Cattleyas Ascania* and *Wellsiana*, *Odontoglossums Pescatorei*, *Coradeni*, and *crispum*, *Oncidium ampliatum majus*, and *sarcodes*, *Angræcum modestum*, *Cymbidium Lowianum*, *Vanda tricolor*, *Epidendrum Wallisi*, *Masdevallia Wallisi*, *Cochlioda vulcanica*, *Dendrobiums stratus* and *Boxalli*, *Cœlogyne Dayana*, and *Cypripedium Schröderæ candidulum* (silver-gilt Flora medal).

Messrs. H. Low & Co., Enfield, showed Orchids in fine condition. *Cattleyas*, *Odontoglossums*, *Oncidium*, *Dendrobiums*, *Cypripedium*, and *Lælias* were in splendid form. The flowers were of high quality and the colours rich (silver Banksian medal). Messrs. Lucien Linden & Co., Brussels, exhibited some good forms of *Odontoglossums vexillarium* and *crispum*. The spikes were very handsome. Mr. F. J. Thorne, gardener to Major Joicey, Sunningdale Park, showed a grand plant of *Anguloa sanguinea* with one of *Eriopsis rutidobulbon*. Mr. W. S. Barrell, gardener to W. S. Ellis, Esq., Dorking, showed a few *Odontoglossums* of fine quality. Small exhibits of Orchids were exhibited by Messrs. F. Hardy, J. G. Fowler, J. Robson, C. L. N. Ingram, T. Statter, W. Cobb, R. Young, P. Crowley, and W. G. Soper.

CERTIFICATES AND AWARDS OF MERIT.

Alyssum saxatile, fl.-pl. (Paul & Son).—This is a good double yellow form of a justly popular plant (award of merit).

Auricula Perfection (J. Douglas).—A grand Alpine variety. The colour is very rich deep crimson with darker shadings. The eye is bright yellow (award of merit).

Auricula Dean Hole (J. Douglas).—Another Alpine of good quality. The flowers are of good size, the colour being crimson with a black patch round the yellow eye (award of merit).

Auricula Ziza (J. Douglas).—This is a good variety. The outer colour is brick red, darkening to black at the yellow centre (award of merit).

Auricula Sweet-scented Yellow (D. Storrie).—A free-growing strain of yellow flowers of various shades (award of merit).

Azalea Madame Joseph Vervaene (C. Turner).—Bright rose is the ground colour of this handsome Azalea. There are abundant splashes and spots of blood red (award of merit).

Azalea Ami Charles Viermeire (C. Turner).—A superb single variety with deep crimson red flowers (award of merit).

Cattleya intermedia Fowler's variety (J. G. Fowler).—A distinct form. The sepals and petals are delicate lilac, and the front lobe of the lip maroon. The side lobes are pale primrose (award of merit).

Lælio-Cattleya Fascinator (T. W. Bond).—A handsome bigeneric hybrid, resulting from a cross between *Lælia purpurata* and *Cattleya Schröderæ*. The fine sepals and petals are rosy mauve, and the superb lip is velvety maroon with a lighter edge. The throat is pure yellow (first-class certificate).

Lælio-Cattleya Hippolyta Dulcote variety (W. Cobb).—In all respects a grand form of the well-known type (first-class certificate).

Radish First of All (Barr & Son).—A white olive-shaped variety of excellent quality (award of merit).

Radish Suttons' Forcing (Sutton & Sons).—Bracketed by the Committee as similar to the above.

Radish Carmine Forcing (Sutton & Sons).—An excellent scarlet olive-shaped variety. The colour is good and the flesh crisp (award of merit).

Radish First of All (Barr & Son).—Bracketed by the Committee as similar to Carmine Forcing.

Radish Wood's Frame (Watkins and Simpson).—Too well known to need description (award of merit).

Sophro-Cattleya George Hardy (F. Hardy).—A bigeneric hybrid between *Sophrontitis grandiflora* and *Cattleya Acklandiae*. The flower is

FIG. 78.—ODONTOGLOSSUM PESCATOREI DUCHESS OF WESTMINSTER.
(See page 412.)

dull crimson, and after the form of *Sophrontitis*. The sepals and petals have, however, the spots of *Cattleya Acklandiae* (award of merit).

Spathoglottis aureo-Viellardi (J. Veitch & Sons).—This is a garden hybrid of great beauty. The ground colour of the sepals and petals is deep creamy yellow. There are an immense number of rose-coloured spots on the petals, and fewer at the tips of the sepals (first-class certificate).

THE TEMPLE SHOW, MAY 25TH, 26TH, AND 27TH.

WE are requested to state that for the eleventh year in succession the Royal Horticultural Society will hold its great annual flower show in the Inner Temple Gardens on May 25th, 26th, and 27th. We are informed also that the desire of growers to exhibit increases every year, and that the officials of the Society have a very anxious task in endeavouring to do justice to those growers who support the fortnightly shows of the Society held at the Drill Hall, and yet at the same time to encourage others also to come forward. The space is absolutely limited by agreement with the Temple authorities; no more or larger tents may be erected. Hence every new exhibitor whose entry is accepted means curtailment of the space allotted to previous supporters.

A catalogue of the show will be given gratis to every visitor, and will contain a notice of new and rare plants entered on or before May 19th. It will also contain a programme of the music to be performed each day. On the first two days the band of H.M. 2nd Life Guards, and on the third day the band of H.M. Royal Horse Guards will perform.

The Judges will meet at the Secretary's tent at 10.30 A.M. on May 25th, at which hour punctually the tents will be cleared of all exhibitors and their assistants.

The Fruit, Floral, and Orchid Committees will assemble at the Secretary's tent at 11 A.M. sharp, and the show will be opened at 12.30.

N.B.—All plants for certificate must be entered on or before Monday, May 23rd. Address, Secretary, R.H.S., 117, Victoria Street, S.W. They cannot be entered under any circumstances on the day of the show.

THE ST. BRIGID ANEMONES.—The variety of colour and the long succession of flowers obtainable from these bulbous plants is remarkable, and the surprise is they get so little recommendation from the Journal readers. I know of no other plant that furnishes so wide a range of colour in the most decided and delicate of shades. True, it is a subject that does not furnish the proverbial "Too much of a good thing," of which "H. H. R." speaks—namely, yellow flowers. It is almost a misfortune that there are none of that shade in these fine Anemones. They, like other forms, possess the trait of closing at night and in dull weather, but only a slight burst of sunshine will change the aspect in an incredibly short space of time, that is when planted in beds or masses, and they are influenced by sunshine in exactly the same way when arranged in vases in the house. A good feature in them, too, is their flowers are borne on stout stalks, and their own foliage enhances their attractiveness either in a cut state or on the plant. Seeds may yet be sown in a box of fine soil or outdoors, but I obtain a larger percentage of plants from a sowing made in a box or seed pan.—R. A.

ROYAL BOTANIC SOCIETY.

MAY 11TH.

THE exhibition at Regent's Park was decidedly superior to its immediate predecessors. The exhibits were charmingly arranged in the big tent, and made a very effective display. As is customary, almost all the groups came from trade growers; indeed private gardeners were perhaps fewer in number than is generally the case. We give a brief reference to the majority of the exhibits. The southern show of the National Tulip Society was held in conjunction with the Botanic, but as we received no notification of the fact we could not arrange for a report to appear in the current issue.

Mr. H. B. May, Upper Edmonton, arranged a charming group of Crimson Rambler Roses, Spiræas, and Ferns. All the plants were well grown, and capitally shown. Messrs. J. Laing & Sons, Forest Hill, were represented by a group of miscellaneous flowering and foliage plants, arranged in semicircular form on a sloping bank. The plants were well diversified, and represented excellent culture. Caladiums, Dracænas, Crotons, Boronias, Ericas, Begonias, Gloxinias, various Orchids, and Crimson Rambler Roses were particularly effective. The Forest Hill firm also exhibited floral decorations. The arrangement of the flowers in baskets, bouquets, and other forms was graceful and light.

Cut Roses and plants in pots were staged by Messrs. W. Paul & Son, Waltham Cross. Amongst the best of the varieties were La France, Maréchal Niel, Violette Bowyer, Madame Montet, Queen Mab, Medea, Duchess of Albany, Enchantress, and William Warden. The bank of Tulips sent by Messrs. Barr & Son, Covent Garden, made a bright display. The varieties comprised many of the Darwin section, some species and a few Parrot Tulips. Very good were May Queen, Rose Pompon, Nabob, Goldflake, elegans, Picotee, Buenaventura, Striped Beauty, retroflexa, The Sultan, and Zephyr. The same firm also sent Alpine plants, Irises and Narcissi in variety.

Messrs. J. Peed & Son, Norwood, made an imposing display with groups of Caladiums and Dracænas. Splendidly grown specimens of many of the leading varieties were observed, but space does not permit of their enumeration. Alpine flowers in variety were staged by Mr. T. S. Ware, Hale Farm Nurseries, Tottenham. The assortment was good, and the plants were of an interesting character. Trilliums, Alyssums, Ranunculuses, Primulas, and others were conspicuous. Messrs. W. Cutbush & Son, Highgate, sent a varied assortment of greenhouse plants, such as Ericas, Oranges, Indian and mollis Azaleas, Boronias, Carnations, Palms, and Ferns.

A most interesting table was occupied by Mr. W. J. Empson, gardener to Mrs. Wingfield of Amptill, with vegetables and fruit. This grower's ability is well known, and the exhibit here referred to well maintained his reputation. The vegetables included Leeks, Rhubarb, Seakale, Potatoes, Tomatoes, Mushrooms, Cabbages, Broccoli, Asparagus, Beans, Radishes, Onions, and others, while the fruits comprised Apples and Bananas. Messrs. J. Waterer & Sons, Ltd., Bagshot, staged a collection of Japanese Maples in small pots.

Mr. W. Rumsey, Waltham Cross, staged Roses in pots and in boxes in good variety and condition. Mrs. Rumsey, Crimson Rambler, Magna Charta, Niphetos, Souvenir d'un Ami, Madame Montet, and Sénateur Vaisse were all well shown. Messrs. T. Rivers & Son, Sawbridgeworth, exhibited Cardinal Nectarines in pots carrying handsome fruits. Mr. C. Turner's Azaleas from Slough were grand. All alike, large and small, were symmetrical and profusely flowered. The Slough firm also sent Carnation Princess May and Rambler Rose Thalia.

A superb group of Orchids was shown by Messrs. B. S. Williams and Son, Upper Holloway. The clean, healthy Odontoglossums, Cattleyas, Lælias, Oncidiums, Vandas, and Cypripediums were producing flowers of high quality. Included in the group were fine Anthuriums, Clivias, Ericas, mollis Azaleas, Cannas, Lilacs, and others. Messrs. B. S. Williams also sent floral devices, mainly composed of Roses, Irises, Anthuriums, Odontoglossums, and scarlet Zonal Pelargoniums. The flowers were arranged with excellent taste. Mr. J. Prewett, Bayswater, arranged a table with Spanish Irises and other flowers.

Mr. G. Cragg, gardener to W. Walker, Esq., Winchmore Hill, sent a good group of Orchids of various kinds and varieties. Mr. Kelf, gardener to Mrs. Abbot, Regent's Park, arranged a group of plants, such as Liliums, Crotons, Caladiums, Palms, Ferns, Gloxinias, and others. Mr. G. Mount, Canterbury, sent cut Roses in his well known excellent style and variety. The flowers were fresh, bright, and fragrant. Mr. A. Smith, High Wycombe, showed Maréchal Niel Roses in good form, and Messrs. A. Young & Co., Stevenage, hardy flowers and Zonal Pelargonium King of Denmark.

IMPROVING TASTE.—It is a favourable sign that the taste for such noble flowers as Pæonies, Crown Imperials, Asters, Hollyhocks, and others of their classes is again rapidly coming to the front. Some years ago there was such a rush for "Geraniums," Coleus, and other tender bedding plants to be used in the flower garden, that it began to look as if the grand old plants of quieter bearing might be crowded aside. Happily such was not to be the case. The bright rivals of the greenhouses found wide popularity—much of it deserved—but at last they have found their proper place even in the best of gardens—namely, they are factors, but not the whole thing, in floral adornment. There is, says "Vick's Magazine," a degree of monotony and lack of expression in a bed of "Geraniums" or Coleus that quite unfits them for being a really satisfying element for large use in the garden.

THE YOUNG GARDENERS' DOMAIN.

BUDDLEA GLOBOSA.

THE effect of this hardy deciduous shrub is very telling just now. We have it on pillars on a north wall. In matters of pruning the same applies to Buddlea globosa as to a Rose—viz., the removal of old wood and the laying-in of healthy young shoots. Buddlea globosa produces its flowers (deep yellow in colour, and globular in form, as its name implies), singly, as a rule, on the wood of the previous season's growth. This is the kind of shrub which should be much sought after in the near future, as it produces a pleasing contrast to the rich wealth of blossom on the more important occupants of the wall—the Cherry trees—at this season of the year.—T. P.

AZALEA INDICA.

NOW that the most important time has come amongst Azaleas I think a few notes on their culture might prove useful to fellow readers. About this time the majority of Azaleas have finished blooming, or at any rate the early varieties have, and it is about these I am writing. The first thing to be done after they are brought from the conservatory, or wherever they have bloomed, is to go over them and remove the old flower stalks, so that they will not prevent the new growth from pushing. After that has been done those which were not potted last year should have attention now, and the others top-dressed.

The compost for potting should be five parts of peat with all the rubbish picked out and one part of silver sand. Take care, before they are potted, to have them moist, and also, if there are any strong shoots, to cut them back. In repotting pick all the outside and sour soil off them, give a slight shift, and ram the compost hard. As for top-dressing, remove a little of the top soil and fill up with the above compost. The next thing is to give water and place them in a warm and moist atmosphere, such as a fernery or vinery that has just been started, where they can be syringed morning and evening to encourage new growth. Leave them there till about the middle of June, when they may be placed outside under a north wall on a bed of ashes. Afford abundance of water, especially in the growing season, as nothing checks the young roots more than drought. It is advisable also, while they are outside, to syringe them every afternoon, as it not only freshens them, but prevents thrips and red spider.—A. U.

LACHENALIAS.

IT is interesting to note the various methods of culture of the same plant by different growers. For instance, two writers in the *Journal of Horticulture* a few weeks past described their way of growing *Centaurea candidissima*. One rooted the cuttings in a cool frame, and the other in a propagating pit, in a temperature of 70°, and both methods were successful.

On page 356 "S. S." describes his plan of growing *Lachenalias*, which is different, but not so widely as in the *Centaurea* case, to that adopted at my last place, with very good results, and is as follows:—Place the bulbs at the end of July in 5-inch pots, using the same compost as described by "S. S.," and plunge them in a bed of leaf soil in a cool frame. When started well into growth remove the plants to a shelf in a greenhouse, with a temperature of 45° to 55°. Supply water very carefully, and when the pots are full of roots give weak liquid manure at each watering. After flowering place the plants in a warmer atmosphere, to finish their growth and form next season's flower spikes. When this is complete place the pots containing the bulbs on a shelf or stage close to the glass in the full blaze of the sun, thoroughly ripening the bulbs. There they remain dry till wanted for potting again. *Nerines* and *Freessias* were treated in the same way.

Lachenalias are increased by seeds or by offsets, these latter being taken off at the potting period. There are many varieties, but I consider *L. Nelsoni* by far the best. A few pots of seven spikes, each with about thirty flowers, are very effective among other plants in the greenhouse.—L. F.

MEALY BUG ON VINES.

IN the whole course of gardening there is nothing which is so annoying, and which takes up so much valuable time to exterminate, as mealy bug. It is one of the easiest of pests to find its way into a vinery, and there is hardly any task so difficult as clearing it out of a house. Still there are ways and means, and no expense of time or labour should be considered too great to keep such a filthy insect from our Vines.

Paraffin has been recommended by some people, but I have seen it most injurious. I am acquainted with a gardener who, going to a new situation, found that all the Vines were infested with mealy bug. He first scraped off as closely as possible all the bark that could be safely removed from his Vines, and then dressed with paraffin and water. The result was the Vines were so badly injured that they had to be rooted out; the bug, however, was left intact. After the bark has been removed almost to the quick paraffin is extremely dangerous, as the Vine is so porous and the oil so penetrating that disastrous effects are almost sure to follow.

The treatment I would recommend is to scrape the rods as thoroughly as possible during the winter, to dress the Vines well with Bentley's insecticide, and then to effectually fill all the holes and crevices with styptic. Make a point of burning all the scrapings, to destroy as many of the insects as possible. The dressing will not injure the Vines, and will destroy all the insects that can be reached. The vinery itself should also be thoroughly cleansed, and when possible painted. As soon as fire heat is applied to the Vines the rods should be carefully examined not less than once a week, and what insects are found killed immediately. They

will be found to emerge from the most unlikely hiding places. This continual hunting must be persevered in if success is to crown the effort. Ants by their industrious habits help to carry the bug all over a house, and if there are any about they are sure to find them. This should be remembered, as it helps one very much in the work of hunting.

The above process will entirely exterminate the pest, and it is the only one I think that will. If an easier way is known to anyone I feel sure he cannot confer a greater benefit on the craft than by making known the secret. In any case I trust my fellow writers will express their views on the subject.—S. S.

A CONGRATULATION.

WHILE sending my hearty congratulations to those two competitors who were successful in obtaining the much-coveted, and I may say well-earned reward of their labours, I cannot help extending my sympathy to the two young men who came so near to the winning. It always seems hard to lose a race close to the winning post. Yet they may be quite differently situated from their more fortunate colleagues. A young man, for instance, who must of necessity spend several hours of his own time at his work during the week, together with his fortnightly or three-weekly duty, has not much time for "Domain" writing after he has spent an hour at his botanical dictionary, another hour perusing the Journal, to say nothing of a little recreation, which in my opinion is necessary both for the mind and body.

This routine, however, is only applicable to the months of March to June inclusive, so it is to be hoped that the Editor will pardon his young correspondents for any falling off during the months named, and he may feel convinced they are not wasting their time, but are filling their pocket books with copious notes (both indoors and out), for putting into MS. form at a more opportune time.

If the two young men take their defeat in a proper spirit it will spur them on to still greater efforts, and we shall have the pleasure of seeing their names after September next among the happy possessors of a lasting memento of their early struggles with "practical gardening literature;" and when earned it will be the more prized by them when they remember the old proverb, "The fiercer the fight the sweeter the victory." Would it not be interesting to us to know the respective ages of all the gold penmen?—T. P.

FRUIT FORCING.

Cucumbers.—If aphides appear fumigate on a calm evening, and repeat early the following morning, having the foliage dry but the floors well damped. With a proper amount of atmospheric moisture, and supplies of water at the roots, red spider and thrips will not give much trouble, but the first with white fly and mildew may be kept down by lightly coating the hot-water pipes with sulphur. Plants that have been in bearing some time will be showing signs of exhaustion, and should be removed. Assist young plants showing signs of weakness by removing the staminate flowers and the first fruits, stopping at every third or fourth joint, cutting off all superfluous and weakly growths. Shading will be necessary for an hour or two in the middle of the day when the sun is hot, especially houses facing south. Little or no fire heat will be required by day, shutting the valves at about 8 A.M., and opening them again at about 5 P.M. Syringe the plants moderately between 3 and 4 P.M., keeping a moist atmosphere all day by damping the floors.

Sow seed for raising plants to occupy pits and frames. A fair bottom heat should be secured by using the less decomposed material from Vine borders or exhausted hotbeds, which, with about a fourth of fresh material, will afford all the bottom heat now required. The nights have lately been cold, in which case close pits and frames as early in the afternoon as safe, not allowing the temperature to exceed 90° to 95°, and afford good night coverings. The bottom heat must be maintained by duly renewing the linings.

Pines.—Changeable weather necessitates careful attention in the cultivation of Pines, especially as regards plants with fruit in an advanced condition, a moderately high temperature and a moist atmosphere being essential to their well-doing. Large well-finished fruits are only to be obtained by close attention to details, especially when the plants are cultivated in pots. Watering will require attending to once a week, but avoid indiscriminate periodical waterings. Plants that have heat at the roots by means of hot-water pipes require more water than those having the heat furnished by means of fermenting materials. Admit air at the top of the house at 80° to 90°, closing at 85°, but unless it be desired to enlarge the crowns do not quite close the house. Fire heat must be employed to prevent the temperature falling below 70° at night, and to raise it to 75° in the day, the bottom heat being kept at 80° to 90°. Syringe the plants two or three times a week, according to the weather, and maintain the atmosphere in such a condition as is likely to secure the perfect development of the fruit.

Peaches and Nectarines.—*Trees Started at the New Year.*—The early varieties, such as Alexander and Early Louise Peaches, Cardinal and

Early Rivers Nectarines, are now ripening, and must not be syringed. The other varieties, such as Hale's Early, Dr. Hogg, Stirling Castle, Dymond, or Grosse Mignonne, Crimson Galande, and Royal George Peaches, with Lord Napier, Darwin, Stanwick Elruge, Humboldt, and Dryden Nectarines, will have stoned, or to make sure, they should not be hurried, and the trees will be all the better if the fruit finish with a night temperature of 60° to 65°, commencing to ventilate at 65°, and not allowing 75° to be exceeded without full ventilation. Tie-in the shoots as they advance, removing superfluous growths. If the shoots are crowded thin them well as soon as the stoning is completed. After stoning maintain good moisture in the house, and water the inside border copiously, mulching the surface with about 2 inches thickness of short manure. Unless it is desired to accelerate the ripening continue 60° to 65° as the night and 65° as the artificial day temperature in dull weather, and 75° with sun heat.

Trees Started in February.—The fruits of these will soon be commencing stoning, and should have the number reduced, leaving two fruits on strong shoots, but one will be sufficient on the weaker. The fruit retained must, in all instances, be best situated for receiving air and light. Thin the shoots where crowded, and tie the growths in loosely. The temperature by artificial means must be kept at 55° to 60° at night, and 60° to 65° by day artificially, ventilating from 65° and fully between 70° and 75°. Syringe the trees morning and afternoon, not allowing red spider to secure and maintain a footing on them, and supply water as required to the border.

Trees Started in March.—With the fruit swelling, attention must be given to thinning, and as it can now be seen which fruits have been properly fertilised by their taking the lead in swelling, thin them to two or three on strong shoots and proportionately less on weaker growths. Afford liquid manure to weakly trees, but vigorous trees should be supplied with water only, and have top-dressings of dissolved bones, always dry and crumbly, and pointing in without disturbing the roots. Remove all superfluous shoots, pinching growths retained to attract the sap to the fruit at two or three leaves, and keeping stopped to one or two afterwards, the remaining shoots being trained to the trellis as they advance.

Strawberries in Pots.—Moisture must not be lacking at the roots of these plants, as when the sun is powerful the fruits are apt to have the skin dried, and do not swell well afterwards. After the fruit commences swelling a brisk moist heat is essential, supplying liquid manure liberally until the fruit changes colour. Admit air freely whenever the weather is favourable, avoiding drying currents. Fumigate late plants if aphides appear, but not when in flower. Water the plants twice or three times a day.

THE KITCHEN GARDEN.

Runner Beans.—Seeds sown early in May are liable to decay or become a prey to millipedes. In anticipation of failures, sow more seeds in boxes or pots under glass, hardening the plants before they become drawn, and plant where blanks occur. Protect the earliest rows from frost. For the main crop sow seeds now in the open, and the sites ought to be heavily manured and deeply dug. It is also advisable to dispose the rows in a convenient position for watering and feeding with liquid manure during the hottest part of the summer. Crowding is a common mistake that should be avoided. If grown in single rows these ought to be as far apart as the stakes used are high, the double rows requiring even more space. Groups of three to six plants disposed 3 feet to 4 feet apart each way and duly staked produce extra heavy crops, and so also do plants thinly grown alongside pathways or trained over walks, these proving both ornamental and profitable.

Beans without Stakes.—Runner Beans can be successfully grown without stakes, provided they are not neglected. If the running growth is allowed to develop and become entangled, the crops will be light and difficult to find. Kept closely topped capital crops should result. Sow on well manured, deeply cultivated ground, in rows 3 feet apart, eventually thinning the plants to about 1 foot asunder. Mulch with strawy litter, this answering the double purpose of conserving moisture and keeping the pods clean.

Peas.—Robust, mildew-resisting varieties should be sown now, these frequently cropping heavily when the heat and drought cripple weaker sorts. The sites should be well prepared by manuring, deep digging, or trenching. Sow the seed thinly in wide deep drills, covering with fully 3 inches of soil. If the rows are disposed from 12 to 20 feet apart, early Broccoli, Cauliflowers, Brussels Sprouts, and other winter greens may cover the spaces between, all apparently benefiting from the association. Thinly grown plants also succeed best, as these branch strongly and bear more continuously than do those in a more crowded state. The young plants must not be allowed to fall about before they are supported first by a ridge of soil, and subsequently by stakes.

New Zealand Spinach.—The true Spinach fails in hot weather, and the New Zealand Spinach should be grown as a substitute. As each plant of this is capable of covering a piece of ground a yard in diameter only a few need be grown to provide numerous baskets of young tops for cooking. The plants thrive on a sunny border only moderately rich, and a few seeds may be sown at once in patches a yard apart each way, or the requisite number of plants can be raised singly in small pots under glass and planted out when large enough, or about the first week in June.

Vegetable Marrows.—Seeds should be sown now, singly in 3-inch pots, under glass in gentle heat, so as to secure healthy seedlings for planting, when it may be done safely. Although Vegetable Marrows are principally grown on beds of manure, or a mixture of decaying manure,

leaves, and vegetable refuse in private gardens, better results usually attend the market grower's methods of growing them on flat ridges in the open. Prepare plants for this method of culture, which will again be referred to, as well as a few to crop earlier in a sheltered position.

Work Among Potatoes.—When the tops of the shoots are through the soil, there ought to be no delay in hoeing deeply among the rows, heavily moulding up the plants soon afterwards. This may be the means of preventing injury by frost, and if the haulm is cut down a portion of the stems will probably be saved, and a quick partial recovery take place. Quick-acting manures, notably soot, may be sown over the ground before it is hoed, and if it does not greatly benefit the earlier Potatoes, its effect will be observable in the successional crop. It frequently pays well to protect the haulm of Potatoes, and this is a desirable practice in the case of either extra early or exhibition varieties. One strong uninjured stem is much to be preferred to two or three comparatively weak ones, the former producing the finer tubers. Protection can be afforded either by branches of evergreens or by 6-inch pots, with their drainage holes stopped, inverted over the plants on frosty nights.

Thinning Advancing Crops.—It is a mistake to delay thinning advancing crops. When quite small Onions, Carrots, Parsnips, and such like draw easily, whether the ground is dry or moist. Leave Onions 4 to 6 inches apart, Horn Carrots a similar distance, delaying the final thinning till the roots are large enough to cook. Intermediate and other large varieties may be 6 to 9 inches asunder; while Parsnips and Beet require 8 to 10 inches. Salsafy and Scorzonera may have 9 to 12 inches, and Turnips 8 to 10 inches. Follow up the thinning with a careful Dutch hoeing between the rows, hand-weeding where necessary.

THE BEE-KEEPER.

THE WEATHER.

THE welcome change in the weather will be appreciated by all bee-keepers, and the threatened drought, which a month ago appeared likely to be serious, is now at an end. What effect will it have on bee-keepers? Stocks, on the whole, are remarkably forward, and should a long spell of dull showery weather set in they will be retarded somewhat; but if they have ample stores, and are otherwise in good condition, the queen will continue laying, and the bees will increase at a rapid rate. May is the most important month in the year to the bee-keeper, as success or failure will depend on the condition of his stocks at that time. Bees hatched during the present month are the workers, which will be at their best for collecting honey from field Beans, White Clover, and the Lime.

FLOWERS ON WHICH BEES WORK.

Many country districts are now a paradise for bees, and the Midland counties are no exception. Within a short distance of our apiary are a great number of Sycamore trees now in full bloom, and the flowers yield an abundance of pollen, and also honey when the temperature is favourable. The bees appear to prefer them to any other hardy tree in bloom at this date. The wild Cherry, too, is now wreathed with bloom.

In the gardens there is no lack of flowers. Apples will soon be a mass of bloom. Plums are now over, and thanks to the bees and the fine weather, the fruit appears to have set well. Pears will soon be past their best; the blooms are exceptionally strong, and as the bees have been on the wing more or less daily, the majority of the flowers will be fertilised. Cherries appear to be setting well. In the beds and borders are numerous flowers on which the bees work freely. Wall-flowers are excellent, so are the numerous dwarf plants, such as Aubrietia, Myosotis, Arabis, the different varieties of Primroses, and many of the bulbs to be found in every garden.

MANAGEMENT OF STOCKS AND SWARMS.

Before entering into the question of hives, it may be as well for the beginner to understand the difference between a first swarm and a cast, or second swarm. The old queen always goes with the first swarm; there is then no queen left in the parent hive, but there are several young queens in their cells in various stages. These usually hatch in about eight or ten days from the time the swarm left the hive. If the bees are numerous and the weather fine they will probably swarm again on the tenth day. This is called a cast, and will be headed by a young unfertile queen. In fact there are usually several young queens with the second swarm, but as soon as they are settled in their new home all but one will be destroyed and cast out of the hive. There will also be some more left in the parent hive, which will often swarm the third time, but as they will be useless for storing a surplus they should be returned to the parent stock. It is better, however, to allow them to remain in the skep in which they were hived until evening, and then shake them into the hive. If treated in this manner they will usually settle down to work, and will not swarm again.

If an increase of stocks is required the third swarm may be placed in a separate hive until the queen has become fertilised, when the old queen may be removed from the first swarm, and the young one from the third swarm introduced in her place, the remaining bees being added to the second swarm. There will thus be three strong stocks for another year each being headed by a young fertile queen.

If the swarms were placed in frame hives, which they always should be, there will remain only the original stock in a straw skep. The bees may be driven early in the autumn and added to other driven bees, which, being put in a frame hive and supplied with stores, will come out strong and healthy the following spring.—AN ENGLISH BEE-KEEPER.

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **S. Rose Hill Road, Wandsworth, S.W.**, and **NOT** to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Madresfield Court Vine Leaves Deficient in Colour (M. B. R.).—It is not unusual for this variety to become pale in the leaves and partially semi-transparent, which probably arises from a deficiency of organic matter in the soil. The best dressing we have found for it has been native guano, applying at the winter dressing or before growth takes place, using $\frac{1}{2}$ to 1 lb. per square yard and pointing in lightly. This with dissolved bones, dry and crumbling, three parts, and two parts double sulphate of potash and magnesia, with a half part of sulphate of iron, mixed, using 3 ozs. per square yard at starting, again after setting, and just after stoning, has given the desired relief, both as regards colour of foliage and fruit.

Making an Asphalt Path (W. J. P.).—A good plan, if not the best, is to procure the requisite quantity of coal ashes and pass them through a quarter-inch sieve; then, when perfectly dry, form a portion of them into a heap, making a hole in the centre, pour in the boiling coal tar and mix as in forming rather stiff mortar, yet thoroughly incorporating and making every part wet with the tar, yet so pliable as to spread readily. The walk should be previously made of the proper form, and a few inches of rubble placed in, leaving space for a 2-inch coating of the asphalt over the rubble, allowing for filling the inequalities. The more even the rubble surface the less asphalt it will take, therefore make the foundation smooth, and let it be dry. Sprinkle over the asphalt coarse sand or, better, fine spar or granite, and when cold pass a light roller over it. After a few days the walk will be solid and waterproof.

Layered Vine (J. J. A.).—We gather that you desire to have a small Vine obtained by layering, bearing one or two bunches of Grapes. If so, you should follow exactly the process shown in the illustration to which you refer—namely, pinching the growths at one leaf beyond the bunch, also all other growths at one leaf, as often as they form, and before the leaves are the size of a florin. "Strong side shoots" must not be encouraged, but prevented. When the pot is filled with roots, take care the soil is not allowed to get dry before watering. Water may be needed twice a day in hot weather, or even thrice as the summer advances, giving liquid manure twice a week. Examine the illustration again, and permit no more extension growth than there shown—i.e., pinch just beyond every small leaf as often as it is produced. Pinching the shoots and supporting the roots are the important points to attend to. Do not sever the layered portion till the Grapes are ripe, and you need not then be concerned about any "bleeding."

Proportions of Sulphuric Acid to Bones (Derby).—Bones broken into small pieces one part (say 1 cwt.), pump or spring water one-third part (say 37½ lbs., or 3¼ gallons), and sulphuric acid half a part (say half cwt.). The process must be carried out very cautiously as regards adding the sulphuric acid, or an accident may happen.

Gasteria Culture (Novice).—You will find that Gasterias, which belong to the Aloe section of the Lilyworts, will do well in a house kept from 45° in winter to 60° and more in summer. They flourish best in sandy loam with a little peat and decomposed dry cow manure, and some lime rubbish and broken bricks—say, two parts sandy loam, half a part of cow manure, and half a part of broken bricks and lime rubbish. The chief care they require is to keep them almost quite dry when in a state of rest in winter. If the pots stand on a damp stone or damp gravel they will absorb enough moisture in the dark months.

Grafting Fuchsias (J. Bates).—You ask "Is it possible to graft Fuchsias?" and we reply most certainly they can be grafted at any time, and almost in any manner, when heat, moisture, and a little shade can be given, and the wood used is thoroughly ripened. The stock should be beginning to grow, and be in advance of the scion in growth. The scion should just be breaking its buds, and the wood should be well ripened. Young wood will do very well if pretty strong; but a good plan is to use some 2 inches of a young shoot, with about 1½ inch of the older wood behind it, making a slice long enough in the side of the shoot to place the old and part of the new wood on it. The slice from stock the scion must be carefully taken off with a clean sharp knife. Tie carefully with bast, make it air-tight with a little clay, cover with a little moss, and damp that frequently.

Unsatisfactory Vine Shoots (G. G.).—The shoots are very pale in colour and stunted in growth, as if lacking nourishment, a not uncommon occurrence when the roots are in a wet and sour border, which sometimes proves disastrous to the prospective crop. To make matters worse the dressing with neat petroleum would tend to prevent the flow of sap, and sometimes has fatal results. It has, we suspect, been injurious to the Vines; but as you have not sent any of the wood that has been treated with the oil we cannot tell to what extent, if any, it may have injured the tissues. Dressing Vines with pure petroleum is a dangerous practice, and it is more than likely it has injured them in your case. If only from the bad state of the border the Vines will recover from their present condition by your improving the medium. A dressing of lime might act beneficially, deferring lifting until a more favourable time.

Cinerarias from Suckers (P. P.).—The plan of raising Cinerarias from suckers has been almost superseded by the sowing of seeds, as seedling plants grow so much more freely. The system about which you inquire ought only to be adopted with superior varieties that it is desirable to keep true. For producing strong offsets the plants should be cut down as soon as their beauty is over, as if left to ripen all the seed that forms this often exhausts them. A cool frame is a suitable position for the cut-down plants, frost of course being excluded, and not an insect must be allowed on the young growths that start from the roots. For encouraging the suckers to root an inch or two of the old soil is removed from the pots, and fresh rich compost added and kept regularly moist. We have often planted Cinerarias out in June in rich soil in a shaded border rather deeply, and they have produced a vigorous lot of offsets, which have formed compact flowering plants for the following spring. The suckers, as to potting, watering, and shifting, require the same treatment as plants raised from seed.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (R. L.).—1 and 2, Varieties of *Iris pumila*; 3, *Berberis empetrifolia*; 4, a form of *Fritillaria meleagris*; 5, *Megasea cordifolia purpurea*; 6, *Lonicera reticulata aureo-variegata*. (X. Y. Z.).—1, *Asplenium viviparum*; 2, *Davallia tenuifolia*; 3, *Nephrolepis tuberosa*; 4, *Cheilanthes hirta*; 5, *Cyrtomium falcatum*; 6, *Pteris umbrosa*. (A. W. H.).—1, *Selaginella stolonifera*; 2, *S. rubella*. (W. W.).—1, *Begonia manicata*; 2, *B. ascotiensis*; 3, *B. odoratissima*. (Reader).—1, *Scilla nutans*; 2, *S. campanulata*; 3, *Aubrietia Hendersoni*; 4, *Doronicum excelsum*. (S. G.).—1, A variety of *Cattleya speciosa*; 2, a poor form of *C. Mendeli*; 3, *Lælia purpurata*; 4, *Odontoglossum Alexandræ*; 5, *O. excellens*. (T. L. S.).—1, *Cassia corymbosa*; 2, *Tritonia crocata*; 3, *Prunus (Cerasus) Padus*. (G. M.).—1, A form of *Fritillaria meleagris*; 2, *Amelanchier botryapium*; 3, *Tiarella cordifolia*. (J. B.).—1, *Brassia verrucosa*; 2, a variety of *Oncidium sessile*. (Capel).—1, *Prunus avium*, fl.-pl.; 2, *P. serrulata*, fl.-pl. (Cray).—Through being well packed in soft green grass the flowers arrived beautifully fresh. The *Rhododendrons* have been splendidly grown, the one unnamed being *R. fragrantissimum*, very fine. The other plants are—1, *Choisya ternata*; 2, *Diosma* or *Adenandra uniflora*. We will endeavour to supply the information you require.

OUR OTHER SELF.

DEAR reader, open your atlas, glance at the two hemispheres, and note your own snug little island away in the northern seas, then take a voyage over the Atlantic till you come to the New World, and look at that stretch of country confined on East and West by the two mighty oceans, on the North knowing no limit save the Polar seas, on the South separated from the States by the glorious St. Lawrence and a chain of inland seas. Read her name and title—"Dominion of Canada," and then reflect for a moment. A daughter mightier than her mother, a land of rich treasures—treasures both mineral and vegetable, and treasures drawn from her inexhaustible fisheries. She is a daughter of whom to be proud, and her children are of our blood. We talk casually of the colonies; have we any but vague ideas of their vastness? We do not grasp the fact of their immensity. We do things on a smaller scale here, and in our self-importance we measure all in our own bushel. By their energy and real hard work the Canadians bid fair to outdo us even in those branches of commerce we have made peculiarly our own. Perhaps we are getting effete; we are certainly getting older.

As Canada ranks farming first in her industries, we thought a few notes on the subject would be at least interesting, if not instructive. For these notes we are indebted to Mr. Williams, who only lately wrote so well of Australia and her farming. Forty times the size of Great Britain! Is there not room for enterprise? Nearly half the population lives by agriculture, and that they carry out their work well is proved by facts, and we think these facts speak louder than words.

There are such diversity of soil and climate that all sorts of farming and market gardening are possible, and space is almost inexhaustible. The Wheat districts are Manitoba and Ontario, and the newer provinces of Assiniboia, Alberta, and Saskatchewan; in these latter there are still nearly 239,000,000 of acres that will make into good farms, and only about 8,000,000 acres as yet taken up.

Canada can grow 5 bushels per acre of corn more than the United States, and Manitoba "hard Wheat" has taken the gold medal against the world's competition at an exhibition in London. Canada has the advantage over us in that she can grow all our grain crops, and Maize in addition. Neither can we yet boast of doing much in the way of outdoor cultivation of the Vine. She has the Barley, British Columbia produces the Hop. She can grow one of the most nutritious of feeding stuffs—i.e., Linseed. She can send us half the cheese we import, and many of our best Apples. Having the food at hand she turns it to good account, and supplies our breakfast tables with admirable ham and bacon—pea fed, sweet, and toothsome. It is said that one house in Canada will often kill in one week as many pigs as are killed in the whole of Denmark. Not only are the pigs well fed, but they are well bred.

Dairy work has of late years made immense strides, and one has only to read the accounts of Miss Maidment's visits to various Canadian dairies to see how well and how thoroughly they have taken up the work in its most scientific form. Butter to Japan! and cheese the world over! good, sound, and free from adulteration. Only a few days from England. No wonder the boundless prairies give us of their fresh beef.

The Board of Agriculture acts wisely and liberally, and does all in its power to forward the best efforts of the farmer. All sorts of subjects are brought under its notice, such as creameries, cold storage buildings (a bonus is given for this), the art of winter butter making. Railway and steamship companies are interviewed, and the value of an English market tested. The system of cold storage is carried out throughout the whole journey—that is, the butter only leaves the cold storage room when delivered out of the steamer in the London docks. The experimental farms "run" by Government number five, and there is another with a college attached at Guelph, Ontario, in the hands of the Provincial Government.

Canada may be truly called a country with a future, and a future of great prosperity. Boundless area, good water carriage, hardworking sons, backed up by a wise Government full of enterprise, ready to place a good and needed article at a fair rate on the world's market. Cold as the Canadian winter is, it has been fully proved that most of the fruits grown in England can be grown there also.

Nova Scotia and Ontario are already noted as growers of capital Apples, and on the Niagara peninsula Grapes as a field crop produce immense yields, and Peach, Plum, and Cherry trees produce fine fruit. Strawberries have become a flourishing industry on the St. Lawrence River and the eastern shores of Lake Ontario. On the western slope tending towards the Pacific Ocean and in Vancouver's Island fruit growing has a great future.

There is a doubt whether Canadian farming will ever find much favour with our English agriculturists. They could not readily adapt themselves to the different aspects of life. The distance from each other and from towns, the practical isolation, and the long though brilliant winters are not what we are used to. The living, too, is rough; and the summer work terribly hard and trying. The class of men best suited for this new country are men who have here been working foremen or small farmers—whose ideas are pretty well concentrated on their work, and who apparently need little or no

recreation. Men of this kind with growing sons, who would readily adapt themselves to the manners and customs of the new country, are the sort who ought to emigrate. They bring as capital a thorough knowledge of their work, and willing and capable hands; and from their early upbringing are not always craving for the luxuries and refinements of life as found in the old country.

WORK ON THE HOME FARM.

"It never rains but it pours" would fitly describe the weather of the past week; there has been no day without rain, and some have been exceedingly wet. The net results have been almost nil as far as farm work is concerned.

Another patch of Potatoes, planted as an afterthought, was only completed with difficulty, and at the third attempt, whilst the condition of the land left much to be desired, the ridges exhibiting that bright polished appearance at the sides which denotes an excess of moisture.

Weeds are growing apace, and as nothing could be done towards stopping their growth, work is fast accumulating. A good wind would be very beneficial to start with, and a dry May would be a godsend and hurt nobody now that we have had such a soaking.

Until the land dries and becomes workable nothing will be gained by taking horses upon it, for the treading is more likely to do harm than good. There is manure to be got out of the yards, however, and if it be required for Swedes, and particularly if it has to be carted any distance, this carting had better be done; the extra turning will do the manure good and pay for the extra filling.

We are troubled just now by a neighbour's bad fence; it is nothing but huge gaps, and the owner has put two rows of barbed wire along his own side of it at such a height that it is a good fence for horses or large cattle, but none for calves or sheep. Our grass adjoining we cannot stock with sheep or young cattle on this account until we have ourselves put a strong thorn beard to keep the animals at home. Our neighbour claims that we are bound to fence against our own stock, and some county court judges would agree with him. Surely it is time the law was made plain on this matter. That every owner of fences should be liable to keep them in such order as to turn back ordinary farm stock would appear to be a ruling that should appeal to common sense, and if the Board of Agriculture would get such a law placed upon the Statute Book, it would do much to earn, and would deserve the thanks of farmers of all grades.

OUR LETTER BOX.

"Strong" Butter (E. A.).—Your rations are perfectly right—that is, the food other than the grass. The reason for the strong butter may be from one or two causes. 1, There may be some herb or plant in the grass obnoxious, such as a species of garlic. It is found in pastures occasionally. 2, And this is the most probable cause: the butter is not thoroughly washed when in a granulated form (pieces the size of pin's heads). With a worker there is no excuse for butter being too moist. Is the water supply good? Has the dairymaid attended any classes for instruction? Has the dairy a concrete floor and no connection with any outside drain? Are all utensils scalded and exposed to sun and wind? Is the milk dealt with at once as it comes from the cow house? Is the cow house sweet and wholesome? and are the milkers particular?

REMARKS.

- 1st.—Overcast early; dull and rainy after 11 A.M., and heavy rain from 3 P.M. to 4.30 P.M.; foggy in evening.
 - 2nd.—Foggy and drizzly early; occasional sun from 9 A.M., and bright afternoon and evening; gale at night.
 - 3rd.—Brilliant early, and fine day, though cloudy at times.
 - 4th.—Dull and damp with frequent rain till noon; sunshine and showers after.
 - 5th.—Overcast morning with spots of rain; very gloomy at times. Steady rain from 3 to 6 P.M., and showery after.
 - 6th.—Brilliant till 10 A.M., and fine morning; generally overcast from noon, with spots of rain at 0.30 P.M. and 4.40 P.M.
 - 7th.—Bright sunshine almost throughout.
- Rather warmer, and with a little more rain, but it is again less than an inch. No week has had an inch since that ending September 4th, 1897, eight months.—G. J. SYMONS.

HERBACEOUS, ALPINE, AQUATIC, AND BOG PLANTS.

All lovers of this class of plants should see the magnificent collection at the **OLDFIELD NURSERIES**, embracing as it does several hundred thousand plants of the very best procurable types. **COLLECTIONS** (our selection only):—12 sorts for hot, dry situations on Rockery, walls, &c., 4/-; 12 for moist, shady, Rockery, 4/-; 12 for sunny borders, 4/- and 6/-; 12 for shady borders, 4/- and 6/-; 6 Aquatic Plants for deep water, 6/-; 12 Aquatic Plants for boggy places, 4/- and 6/-; 50 fine showy Border Perennials, in 50 vars., 15/- and 21/-; 100 ditto, in 100 vars., 35/- and 42/-.

A CATALOGUE, giving a large mass of information about them, may be had post free.

CLIBRANS, ALTRINCHAM AND MANCHESTER.

HOOPER'S PANSIES

THE FINEST STRAIN IN THE WORLD.

Has been Awarded upwards of 50 Medals by R.H.S. and R.B.S. of London.

12 Grand Exhibition Varieties, 3/-; 12 Champion, 4/-; Seed saved from 2000 Exhibition Varieties, 1/-, 2/6. Packet, free for cash.]

HOOPER, Pansy Grower, BATH.

THE "SPROUGHTON" HOE.

Simpler than the Dutch Hoe and much superior. The most perfect Duplex (Push and Draw) Hoe yet made. Highly approved at Chiswick (R.H.S.), and at the Royal Gardens, Windsor. Strongly commended by Sutton & Sons, Mr. E. Molyneux, and other leading horticulturists. Copies of testimonials from Rev. A. FOSTER-MELLIAR, Sproughton, Ipswich. Price 1/10 each. Of all Ironmongers, or of

Messrs. RANSOMES, SIMS & JEFFRIES, PRINCES STREET, IPSWICH.

DEFY THE BIRDS by Buying our Noted **ROTLESS TANNED NETTING**, as supplied to the Principal Gardeners in the Kingdom. Orders over 5/- value are sent Carriage Paid. 100 yds. by 1 yd., 3/-; 200 yds. by 1 yd., 6/-; 300 yds. by 1 yd., 9/-. Can supply any length and width. — **UNIVERSAL SUPPLY ASSOCIATION**, East Street Works, Reading. (Name Paper.)

Bath's DAHLIAS, BEGONIAS, &c.

DAHLIAS.

My Collection of Dahlias is one of the most select in the Kingdom, and contains the cream of all varieties, old and new, all inferior ones being discarded. The plants are strong and healthy, and warranted to give satisfaction.

CACTUS DAHLIAS.

This new class is no doubt the most popular of all the Dahlia family, and for garden decoration as well as for cut bloom its beautiful flowers are invaluable. The following sets of Cactus Dahlias are the best ever offered:—

BATH'S NOVELTY SET

Of 12 lovely new varieties for 7s. 6d.; 6 for 4s., carriage paid.
EARL OF PEMBROKE, bright velvety plum.
BEATRICE, pale rose, lighter in centre.
MRS. WILSON NOBLE, lovely pinkish salmon.
MRS. MONTEFIORE, rich glowing scarlet.
MRS. BARNES, beautiful pale primrose.
MRS. FRANCIS FELL, pure white, with a faint disc of yellow at the base of the petals.
ENDYMION, bright cerise, very fine.
J. E. FREWER, vermillion, having a velvety gloss.
MABEL KEITH, buff, suffused with soft pink.
MRS. GORDON BLOANE, terra-cotta pink, fine.
VALKYRIE, rich cardinal, shaded rose.
FUSILIER, bright coral-pink.

BATH'S POPULAR SET

Of 12 very fine varieties for 5s.; 6 for 2s. 9d., carriage paid.
LADY PENZANCE, soft yellow, of faultless form.
MARY HILLIER, clear rich salmon.
MAYOR HASKINS, brightest glowing crimson.
GLORIOSA, brilliant scarlet, perfect form.
FRANCIS HUMPHRIES, bright orange, a magnificent variety.
MRS. PEART, white, splendid form.
MISS JANE BASHAM, brick-red, base of petals salmon-pink.
MATCHLESS, the darkest velvety maroon.
ROBERT CANNELL, bluish shade of magenta, extra fine.
PURPLE PRINCE, rich deep purple, very fine.
LADY H. GROSVENOR, golden amber, a delightful colour.
MARQUIS, rich fiery crimson.

POMPONE DAHLIAS.

These are superb for cutting, and being small and compact they last a long time. They also make a splendid display in the garden; the dwarf-shaped bushes, covered with brilliant coloured flowers for two or three months, look like huge bouquets.

Set of 12 lovely varieties for 4s.; 6 for 2s. 9d., carriage paid.
OTHELLO, bright crimson, perfect.
PURE LOVE, beautiful lilac-rose.
MARS, vivid orange-scarlet.
ROSALIE, pale primrose.
GEORGE BRINKMAN, pure white.
FASHION, bright orange.
GOLDFINCH, yellow, very pretty.
KATIE PARNHAM, white, tipped lake.
GUIDING STAR, pure white.
DARKNESS, very dark crimson.
OLANTHE, deep orange, shaded buff.
DORA, yellow and white.

SINGLE CACTUS DAHLIAS.

Quite a new type. The petals of this type, in place of being rounded and recurved (as in the ordinary Single Dahlias) are long, twisted, and beautifully incurved, like those in the true type of Double Cactus.

12 choice varieties for 5s.; 6 for 2s. 9d., carriage paid.
DECORATIVE DAHLIAS.

Splendid for garden decoration. 12 for 5s.; 6 for 2s. 9d., car. paid.

SHOW AND FANCY DAHLIAS.

Finest exhibition. 12 for 5s.; 6 for 2s. 9d., carriage paid.

SINGLE DAHLIAS.

Very graceful, fine for cutting. 12 for 4s. 6d.; 6 for 2s. 6d., car. paid.
For COMPLETE LIST OF DAHLIAS, with full cultural notes, see my GENERAL CATALOGUE, free on application.

BATH'S BEGONIAS.

As bedding plants Begonias are indispensable; they totally eclipse the Geranium both in colour and in flower. They are also well adapted to conservatory and greenhouse decoration. The strain I offer is one of the best. The flowers stand erect on short-jointed foot-stalks; they are large, of fine circular form, and the plant is very dwarf and sturdy. Single, fine for bedding or pot culture, in six distinct colours, 6 for 2s. 9d.; 12 for 5s., carriage paid. Double, for bedding, mixed colours, 6 for 4s.; 12 for 7s. 6d., carriage paid.

CHRYSANTHEMUMS (Summer Flowering).

These are specially adapted for blooming during the late summer and early autumn. They give a marvellous display of bloom from July to the end of October, or until the frost cuts them down. They are also suitable for conservatory and greenhouse decoration, and for cutting are invaluable. Plants should be obtained from April to June and planted in any good garden soil; will require no further attention beyond carefully staking as they grow. My Collection includes only those which are TRUE EARLY-FLOWERING VARIETIES. My selection, in 12 lovely varieties, 3s. 6d. per doz., carriage paid.

DWARF CANNAS.

No class of plants has come to the front more rapidly than Dwarf Cannas, and the vast improvements which have recently been made in these account in a great measure for their popularity. The beautiful foliage much resembles the Dracena, which, with its brilliant Gladiolus-like flowers, at once arrests attention. Their culture is very easy, as they simply require planting out in May or June and lifting before frost sets in, treating the tubers in the same way as Dahlias; or, if potted up, they will enliven the conservatory or greenhouse the whole winter. 1 doz. choicest named varieties, 12s.; 6 for 6s. 6d., car. paid. 1 doz. very good varieties, 7s. 6d.; 6 for 4s., car. paid.

Write for my COMPLETE CATALOGUE, sent post free on application.

All Goods are Carefully Packed and sent Carriage Paid for Cash with Order.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St. London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

NOTES ON MUSCAT GRAPES.

IT is hardly possible to have Muscat of Alexandria, still the Grape *par excellence*, ripe before June. Black Muscat (Muscat Hamburg) may be ripened by the end of April, but it sets its berries very indifferently at an early season. Madresfield Court may be described as an improved Black Muscat in the matter of setting and swelling the berries, but it cannot be classed as a Muscat in the same sense as either of the two mentioned. Canon Hall forces well, and has some Muscat flavour, being, when properly finished, a magnificent Grape, and an excellent companion for Muscat of Alexandria.

Crops of Muscat of Alexandria started in December are now ripening, and the Vines must not lack water at the roots. Examine the borders every week, and if moisture be necessary give water or liquid manure liberally and warm, the drainage being free and the border materials of an open nature. The Muscat class of Grapes appear to revel in lime or calcareous gravel where the subsoil is red with oxide of iron. The Vines then appreciate fish and bone meal as top-dressings, about ½ lb. per square yard in the winter, or before the starting period. This suffices for the year, supplemented with phosphate of ammonia and nitrate of potash in equal parts three times during the season—namely, at starting, when the Grapes are set, and again when half swelled or on first signs of colouring. An ounce per square yard of the mixture suffices, or that quantity to 4 gallons of water given to the area stated.

The Grapes now changing for ripening may not need a very liberal supply of nutrition for present demands, but that which is given promotes the health of the Vines. I have found that Muscats like sulphate of lime, and give better results with gypsum than without it. Whether it is the lime that goes to feed the Vines or acts in the soil by keeping it sweet and providing available potash makes no difference. In dissolved bones there is about 25 per cent. of sulphate of lime, and in mineral superphosphates not less than 45 per cent., the latter being best for quick action or use with

nitrate of potash. I do not know how the lime causes the better utilisation of the potash, but the fact remains, and certainly helps the Vines against shanking in the berries. An analysis of natural soil in which Muscats thrive unusually well, shows 34 per cent. sulphate of lime. The soil is a calcareous gravel and contains 3.63 per cent. of iron, but this amount of iron seems to favour the shanking where the sulphate of lime only amounts to 18 per cent. I have suffered terribly from shanking in early Muscats, and have not found anything of any use against it but the superphosphates and gypsum, and the information may be of use to somebody. But there is another side to the effects of superphosphates. An excess may cause "browning," the leaves and young shoots turning hard and brown on young or vigorous Vines, and arresting their progress. There can be nothing simpler than this. Do not overdo the superphosphate, and to prevent shanking use sulphate of lime with a little sulphate of iron (if not naturally in the soil) and magnesia, taking care to ammoniate the iron by supplying organic manures.

When Grapes are ripening is the time when shanking declares itself, hence the foregoing notes are in season. It is equally seasonable to say that it is of no use to apply anything to a close pasty border soured by lack of drainage. Drains for such borders, and a dressing of gravel mixed with the soil, will beat all the fertilisers in existence. I have tried most of them, and found a suitable soil staple of more consequence than all the science in the world. But is not the cultivation of the soil a science?—well, an art, a step up from theory to practice! If the soil be sour, and cannot be interfered with now, do not hesitate to give a dressing of air-slaked chalk lime. A pound or more to the square yard will not hurt anything except the sourness, and may have a most beneficial effect on the Vines. A lighter dressing of lime to close borders annually may prevent the necessity of lifting the Vines, as many borders are too close simply because crumful of organic matter which water cannot pass through freely and wash away by the drainage, not perhaps over-good, yet sufficient for practical purposes. I mention these expedients, as few gardeners are overburdened with men in these days, and many proprietors have a strong objection to having things upset and incurring expense that can by any means be avoided. I have seen old Vines greatly improved by dressing unctuous borders with best chalk lime, and, on the other hand, known some poisoned by applying a heavy dose of magnesian lime. A light dressing of this, not exceeding half a pound to the square yard, does good when heavy dressings of stable manure and thick liquid from manure tanks have been applied to the borders.

Another thing I should like to mention, and that is the exercise of judgment. Some Vines, in a sodden and sour border, that shanked in the berries seriously, were kept so dry that the soil cracked. This had a good effect the first year, and better the next; indeed, they outgrew the shanking, simply through air getting into the soil, not a drop of water being given to the border until the Vines showed evidence of wanting it by the foliage becoming limp, or even slightly flagging. These trifles may seem insignificant to growers who have nothing but fair sailing, and can command as much material and labour as they please, but I have found that circumstances greatly alter cases, and many persons gain success through adaptation of procedure calculated to overcome the difficulties with the means at command, while not a few fail under favouring conditions by lack of sound judgment and failing to discover the cause of a misfortune.

The Editor may perhaps have seen some Vines ruined by over-feeding, also others practically effete for lack of support, and may therefore find a place in "our Journal" for these records of experience. I have, however, had much trouble with Vines through shanking, and confess to never being able to grow early Muscats without losing a few berries. Some people never have any trouble of this kind, or if they have they keep it in the background and put forward nothing but the best examples of their success. I think this a mistake, as than the recording of failures, their cause and future prevention, no information can be more useful. Grapes do not usually shank outdoors, therefore the affection must arise mainly from cultural errors. Something must be wrong, either in the soil staple, its constituents, the

manures and moisture applied, or in the management. It is just as well to look straight at these things and admit the facts, instead of hiding them when they are not to our liking. Muscat Grapes are twice as difficult to grow as the vinous Alicantes and Gros Colmans, and the more difficult to grow, the more shanking.

The temperature, when Muscats change colour, should be kept at 65° to 70° at night, 70° to 75° by day artificially, and through the day from 85° to 95° from sun heat. A circulation of air must be maintained constantly warm and rather dry, but not too dry, air being essential to the perfection of the fruit. If the sun is very powerful, and the panes of glass large and clear, a single thickness of herring nets drawn over the roof will prevent scorching of the leaves and berries, which is often occasioned by the deposition of moisture on them. This is also a common cause of spot, indeed necessary for the germination of the spores of the spot fungus. When the Grapes are likely to suffer through damp arising from the border, mulch it with a little short dry material, preferably clean dry straw coarsely chopped. This and some air constantly enables us to have Madresfield Court free from cracking, and it also answers for the "Duke," a grand Grape, too seldom seen.—PRACTITIONER.

CUCUMBERS IN COLD PITS.

PITS in which bedding plants and early vegetables are now growing will soon become vacant, and it therefore will be for us to look ahead and determine how we can turn them to the best account during the summer months. A considerable amount of such space will be required for Primulas and Cinerarias, which are now growing rapidly, and will every few weeks require a greater amount of space; but after making due allowance for such contingencies there is usually a considerable amount of pit room which can for a few months be devoted to Cucumber or Melon growing.

In the present article we will deal with the culture of the first named, which as a rule gives more satisfactory results when grown in pits or frames than Melons do, although the latter in skilful hands will in fairly favourable seasons succeed splendidly. What they often do not receive is that close attention to detail so necessary to insure success. In one noted fruit growing establishment, where I served for some years as foreman, Melons are largely grown in cold pits, and though the seasons were not always favourable we never experienced a failure. But let us return to the Cucumbers.

Under pit culture, with the plants trailing over the soil, it is just possible to produce many Cucumbers quite as fine and straight as those from plants grown in houses, though there will generally be a greater percentage of second quality. Those who contemplate planting Cucumbers in pits as they become vacant should take steps to have the requisite number of plants ready as required. If no young plants are advancing seeds ought to be sown at once, and if the young plants are grown in strong heat they will be ready for planting three weeks from the date of sowing the seed. The sowing is, however, sometimes not done "just in the nick of time," and when it is important to raise a set of plants as quickly as possible I insert cuttings, place them in strong bottom heat, and obtain well-rooted plants in about ten days. The varieties I prefer for frame culture are Telegraph, Rochford's, and Lockie's Perfection.

Assuming that we have a pit to deal with from which early Potatoes have been dug, a great amount of preparation will not be needed. The soil requires to be simply levelled, and small mounds or fresh soil placed in the centre of each light. This fresh soil may be quite a simple mixture; good turfy loam with a fourth of manure and a little soot added answers admirably. I always like to plant two plants to each light, because if one should through any cause come to grief the other quickly fills up the blank space.

When the main shoots have grown a few inches in length I remove the point, and take two shoots from each plant, stopping these when they get to within a foot of the edges of the pit. Alternate laterals are then removed, and those left stopped at one or two joints beyond the fruit; according to the space at command for leaf development. Before the growth has extended very far I usually add the additional soil required. This is formed of the same ingredients as already given, and a 4-inch layer spread over the old soil, and made moderately firm, answers admirably.

Much of the success of Cucumber culture in cold pits depends upon following an intelligent system of ventilation. A golden rule is to give air early and to close early. A chink given early prevents the temperature from rising rapidly, and on "catchy" days renders the admission of large quantities of air unnecessary. Many who grow Cucumbers are rather timid about closing the lights too early, but I

never hesitate to do so at 2 P.M., during the hottest day in summer. But before doing so those plants that require it are watered, and a thorough syringing given to every part of the plants, as well as the sides of the frame. On dull days the frames are closed without syringing, and after a wet day or night a little air is always admitted for a few hours to dry superfluous moisture.

When the plants are carrying heavy crops weak liquid manure should be applied almost every time water is needed, giving a little soot water occasionally by way of change, and whenever red spider is inclined to be troublesome syringing with clarified soot water will usually effectually keep it in check. It is most important to assiduously remove the small fruits which cluster round the larger ones, as well as the male flowers; if this is not done a great deal of the energy of the plants is absolutely wasted. Deformed fruits should also be removed, as they exhaust the plant quite as much as a shapely one, and when fully grown the former are no credit to the grower.

By attending to these matters, and removing worn-out growths to make room for young shoots, good crops may be grown in frames throughout the summer with comparatively little trouble. A simple method of preventing the under side of the fruits from being blanched by resting on the soil is to place "props" under them. These are easily made in the following way: Cut some stakes about an inch in diameter into lengths of 9 inches, nail across the top a piece of lath 4 inches in length. If the stake is then thrust into the soil the Cucumber rests securely on the horizontal lath.—H. D.

THOUGHTS FOR YOUNG THINKERS.

POSSIBLY, even probably, in submitting a few thoughts to the consideration of young gardeners, there is apparently little to add to what has appeared in the *Journal of Horticulture* on their behalf. But we do not stand still. Things have lately appeared in its pages calculated to set even old gardeners thinking. Those who are in the autumn of life look back on the past, and muse on obstacles encountered and triumphs achieved by the old masters. Grand old men were many of these—devoted florists, and painstaking workers in all departments. Young men—gardeners in the springtime of their career—look wistfully and wonderingly into the future. What will this future be? One of their fixed thoughts, deepening into conviction, should be that it depends on themselves, for "all things are possible to youth."

In opening up a field of thought to young thinkers we may consider in the first place some of the present changes in gardening, as to whether they are of the spasmodic kind, frequently occurring in all phases of life, or whether they are likely to be permanent in their action. Calm deliberation yields prompt decision, on which vigorous action may be taken if the necessity for such can be made apparent. Change begets change. The fine old gardening establishment of a nobleman may pass into the hands of a merchant. The old-time gardener, pure and simple, is not prepared for the change that this involves. The gardener's duties have now to run on severely practical lines, dictated by business instincts, and the gardener may have to be electrician and a dozen things to boot. Not a "gardener's business" may be remarked. True. A gardener's business is gardening, or ought to be from our point of view; but now that the old order of things is rapidly giving way to the new, what do we find?

Having passed from one to the other, I can speak from experience, and "gardening alone" would fail me absolutely in meeting modern requirements. Moreover, I know that some of the best situations with which I am acquainted are filled by men of many parts, who, in adapting themselves to the change, hold positions of such high responsibility that, nominally servants, they are virtually the master's deputy, managing the intricate machinery of a modern establishment in a way that is appreciated by the man of business methods. That fact may well afford food for thought by young thinkers; but those more particularly in view should not aim too high at first in seeking accomplishments before they have acquired what may be termed the rudimentary essentials of the young gardener's education. He must first be a gardener, for if not that he is nothing, but he can be that and more also when occasion arises. If not, he is, of course, the gardener and nothing more, easily dispensed with nowadays, as many know too well. But, and mark this particularly, the man who identifies himself closely with his master's interests over a wide field, as occasion arises, is practically indispensable. Common sense will prevent the misconception that a man cannot be done without, but many a good servant leaves a broad margin of usefulness blank, which often tends to swell the chapter of accidents, the sequel to which is, "Out."

There are a hundred ways and as many opportunities for a man to adjust himself to a position in life. They are, too, generally as open to avoid as they are to embrace. How many openings are there in

the garden alone frequently occurring? Planning houses, heating arrangements, landscape work, and other things, all of which when broached a man can easily shift to other shoulders by remarking that he does not profess to be a builder, engineer, or anything than a gardener. Let us hope he may be fortunate, though it may well be remembered that while such a confession might suffice in the brave days of old, it does not suit modern masters of the merchant type, who are now, so far as situations are concerned, in the ascendant. Hundreds of places there are now where new masters rule by new methods, and the old, stately ways, have been ousted by that practical, vivacious energy running concurrently with up-to-date requirements. In this matter of change alone, there is, surely, matter for reflection, but greater changes still have yet to engage our attention.

I fear many young men have thought they would like to be gardeners, but when the opportunity has come have thought little more about it, leaving the rest to fate or chance, as they drift along in the current of events. This is not satisfactory, for the majority of them hope sooner or later to attain to the higher ranks of gentlemen's gardeners; but as the supply far exceeds the demand, it is vitally essential that they should pause and consider the accomplishments necessary for them to win a prize in so fierce a competition.—AN OLD BOY.

(To be continued.)

WOMEN GARDENERS AND THE EAST COWES HORTICULTURAL ASSOCIATION.

THIS Association has published a manifesto in the "Isle of Wight County Press" against the manufacture of women gardeners in a training college, going on to say—"It is most astonishing to find that this question of women gardeners is allowed to proceed with, to our mind, its damaging effects, uncriticised by the gardening Press of this country. It is ridiculous to suppose that a woman, after receiving three years or more training, one-half of it theory, in a particular college, has acquired all the knowledge necessary either to conduct a well-kept private or public garden in all its cultural details. But the most lamentable fact appears to us to be that a college for producing such results as above described should be promoted under the combined management of three County Councils. If technical education grants are to eventually become the means whereby the hard-working gardener after years of deep interest and devotion to his profession is to be supplanted by a youthful feminine population, the money thus granted had far better be diverted to other channels."

There seems to be room for a few words of comment on at least three points in the manifesto.

1, As to the silence of the gardening press. Possibly its conductors, who are not entirely without experience in matters of the nature indicated, may be slightly less disposed to give such bold advertisements as the Cowes Horticultural Association does to college methods, which its committee condemns. The institution which it names will be obliged by the prominence thus given by Isle of Wight friends.

2, As to the effect of the training. It would indeed be ridiculous to suppose it could make one fair student in a hundred half competent in twice three years for the successful discharge of the varied duties of a long, well, and practically trained gardener. This ought to be regarded as an element of weakness on the one side, and of strength on the other; and would seem to be all in favour of the continuance of the "man" gardener. The British are, in the bulk, a practical people, and only a limited number of them are satisfied to purchase labour, skill, or anything else, except on the principle of value received.

3, As to "three County Councils" promoting and managing a nursery for young ladies, it may be said that scientific and practical instruction in gardening is afforded to both sexes by several County Councils, and appreciated by both. If the Committee of the Cowes Gardeners' Improvement Association are in possession of evidence that public money is applied to speculative institutions to relieve shareholders of financial responsibilities, it is open to the Committee to place the facts before the Government, and in this they would no doubt secure the co-operation of their parliamentary representative.

While we believe there is nothing the gardening press would refrain from doing, which could be properly and usefully done to raise the status and improve the positions of genuine "men" gardeners, we are unable to share with Isle of Wight intensity in fears respecting the "women." True, we do not know how many of the masculines have been displaced by the feminines in the "Garden Isle," but whatever the number, we think the time is distant when the gentle sex will figure largely in horticultural directories. In the meantime we would fain hope that the Island gardeners, who are very good and very earnest, may derive a modicum amount of consolation by the calm contemplation of the

little (or great) fact that there are a hundred times more "men" cooks than "women" gardeners.

In these and future competitive days it may be well to face boldly the ever-growing probability that in contests for positions in various professions and vocations the "best men will win," even if, to speak paradoxically, some of them are women. It seems to be difficult nowadays to define the sexes by occupations; and as a matter of fact we have heard present day gardeners refer to more than one brother in the craft as an "old woman."

We are sorry for their own sakes, more than for the men, that so many young ladies are being led into the belief that by payment of college fees for two or three years they can live happy, arcadian, lucrative lives in the servitude of gardening. A few may do so (and we would much rather see them happy than miserable), but many are bound to be woefully disappointed, as are hundreds of unfortunate men. If a number of educated women would, by proper training, make themselves equally expert with men as high-class cooks (as they might), they would find the "profession" much more remunerative than gardening; and then, perhaps, issue a manifesto against the muscular sex presuming to compete with them in such feminine employment.

COB-NUTS AND FILBERTS.

NUTS in this country may be said to grow under three conditions. First, wild, and as such they may be found in varying quantities in almost every copse in the kingdom, as no plant is more generally prolific than the common Hazel. Secondly, they may be found in the majority of private gardens in various parts of the country, though it may be safely added that in few do they receive the best attention in pruning and training, and consequently the results are generally uncertain. Thirdly, they are grown for profit, and this phase of Nut culture belongs almost entirely to the county of Kent, to the end that in their season Kentish Cobs are a household word, and find ready sale. Yet it is a reasonable question to ask why they are not generally cultivated in other counties. The plant requires no extraordinary conditions of soil or culture, and succeeds on sites that would be quite unsuitable for other kinds of fruit.

With reference to Nut culture in private gardens the method of treatment, generally speaking, differs widely from that adopted by the Kentish fruit grower. The fact that Cobs and Filberts, which are subjected to no regular system of pruning and training, will and do produce fairly good crops of fruit, is very often put forward as an argument that pruning periodically is not necessary, and it is when we come to reckon up the weight per acre, taking one season with the other, that we see the advantages of a properly trained bush to begin with, followed by systematic pruning. The private garden custom, which I treat as general, though there are doubtless many exceptions, allows the bushes to make free unchecked growth, which for a few seasons may be quite right, but in time they become overcrowded, and represent a thicket, the inevitable consequence being that the only Nuts produced are at the extremities of the branches, and the whole interior space is wasted. This state of affairs continues till the bushes have grown out of bounds, and have to be headed back, and the intervening seasons, till fresh bearing wood is made, are lost.

Again, Nuts are not considered a high-class crop in gardens, and therefore do not receive the same care in the choice of soil and situation as falls to the lot of Apples, Pears, and so forth. It is a mistake to fancy that Nuts will prosper anywhere, simply because they will grow where other fruits will not. I have seen plantations of Filberts in cold, water-logged, clayey soil, where sunlight rarely penetrated. Growth was luxuriant enough, but no fruit followed, and Nut culture was abandoned as hopeless. In another district, north of the Trent, in a light shallow soil resting on sandstone, Filberts did splendidly, and though the Kentish system of training was unknown, good crops were gathered most seasons. Similar instances could be quoted from other districts, which makes it appear strange why Nuts as a market crop should be confined practically to one county.

Though Nuts are accommodating as regards soil, and succeed well in a brashy stony medium on sunny banks and hillsides, they demand food—an item very often overlooked in private gardens, and there is no doubt that the success of Kentish Nut orchards is due largely to the substantial dressings of farmyard manure, rag waste, and chemicals they annually receive. Having drawn comparisons between Nuts as they are generally treated at the hands of the private gardener and the market grower, it will be well to trace the plant's life from infancy, beginning with propagation.

There are several methods of raising Cob Nuts and Filberts, the two most common being from suckers or layers. Of these the latter course is recommended, as bushes raised from suckers generally show a tendency to continue throwing up growths from the base, and this is not so marked when propagated from layers. To raise plants by this method shoots two or three years old are notched and pegged

down in the autumn, covering with 3 or 4 inches of soil. By the following autumn they are rooted, and may be removed to a nursery bed, and planted in rows about a yard apart and 2 feet asunder in them. It is here that the bush is subjected to its early pruning and training, as a good foundation must be laid, without which it is useless to hope to get a well-shaped and profitable bush or tree. Suckers are the young growths emitted from the base of the old bushes, and if these are taken off in the autumn with a few roots attached, and planted in nursery rows, they continue growing till large enough to be removed to their permanent quarters. Probably this is the quicker way of raising Nut bushes, but for the reason stated I prefer them from layers. In any case the nursery bed should be deeply cultivated, and, if needed, farmyard manure incorporated with it. The situation also should be sunny, so that the conditions may be as favourable as possible for the making of stout healthy bushes, in the best form for bearing.

Whatever differences of opinion may exist on pruning generally, I think that most persons agree that the time when the careful use of the pruning knife is necessary is during the first few years in the life of a fruit tree, or while the foundation is being laid. Nuts are no exception, and it is in the nursery bed that steps are first taken for the formation of the thousands of model bushes that continue fruiting for years in Kentish plantations. In the first place, it is necessary to have a clean stem about 18 inches from the ground, consequently all the lower buds are removed at the time of transplanting the layers in the autumn. In the spring the tops of the plants are also removed, leaving, say, half a dozen buds. It is from these that the first branches are obtained. Three or four of the stronger, dispersed at even distances, are sufficient for the first season, and the remainder may be removed. The shoots which are to form the main branches are allowed to extend to their full length, but all weak side growths may be pinched off. No strong shoot is required in the centre, as Nut bushes are best grown cup-shaped, with the middle open. Pruning the next season is composed of cutting these leading shoots back to half their length, which will cause the emission of strong breaks below, and these breaks are to form main branches. It is important to avoid overcrowding, therefore if six or eight leading branches can be insured the second season they will be ample.

The foundation is now laid, and the plants in their permanent quarters, where they remain to become well established before transplanting. All young plants will not form good specimens, and when the heads are weak it is a good plan to cut them back and get fresh growth from the main stem. Up to this time the bush has really been going through the process of formation, with the leading branches evenly disposed in cup-shape and the centre open. Pruning and other details will be referred to in a future issue.—A WORKER.

ROYAL HORTICULTURAL SOCIETY.

MAY 10TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair); Mr. A. Sutton, and Rev. Professor Henslow, Hon. Sec.

Morchella, Species.—Some specimens were sent of a small species of this fungus, which appeared in a garden bed; but the locality was not recorded.

Peas, Decayed.—Mr. Cooke, The Croft, Detling, Maidstone, forwarded some young plants of the "American Wonder," which had failed to grow. They were sown last November, and while many are doing well, others close by turned a sickly yellow. Mr. Sutton observed that his experience was that no wrinkled Peas, as the above, were suitable for autumn sowing; the skins, being more delicate than those of round Peas, will not stand the winter so well. This was, therefore, the probable cause of failure.

Freesia Bulbs Arrested.—Mr. F. Egbert Hollond, Satis House, Yoxford, sent some bulbs which had been planted last July, had never thrown up any leaves, but had formed fresh bulbs upon the old ones, which had withered. It appeared to be a case common in Potatoes, when it is called super-tuberation; fresh tubers being formed at the expense of the old one. It was possibly due to the Freesia bulbs having been planted at the wrong time of the year, energy being expended in a wrong direction.

Cineraria Hybrids.—Mr. James, Woodside, Farnham Royal, Slough, sent a collection of hybrids raised between (*C. cruenta* × *Garden C.*) ♂ × *C. lanata* ♀. They were a small selection of a numerous progeny, the greater number of which were said to resemble the garden form; but the present ones had a tomentose stem and branches, as well as the under surface of the leaves, which also in form resembled *C. lanata*. The blossoms were rather small, some being a pure white, others mauve, but remarkable for their quantity. Unfortunately the best plant with white flowers refuses to set much, if any seed; but it was hoped that Mr. James would persevere and try to establish a new race, which would certainly be attractive from the silvery appearance.

Begonia Leaves Diseased.—Mrs. Caddy, Lion Gate Gardens, Richmond, sent some leaves decayed round the margins. They were forwarded to Mr. W. G. Smith for further examination.

PROFITABLE FRUIT GROWING.

(Concluded from page 403.)

My plan of occupying a whole house with one Vine with the least possible loss of cropping space would be to plant the Vines along the front in the usual way, about 3 feet apart. Crop and prune in the usual short spur system until they have reached the top—which may be about five years from the first year of fruiting. Now select a healthy Vine about the centre of the house. From this Vine allow leaders to grow at right angles from both sides, beginning at the bottom wire and continuing every 18 inches to the top. Allow these leaders to grow 6 feet, then stop. Disbud and make room for them where they cross the two upright rods on each side of the selected one. Crop the rods on each side of them heavily, and cut out as soon as the fruit is off. At pruning time cut back the horizontal canes to 3 feet. Disbud all growth from the under sides, allowing laterals with fruit to fill the 18 ins. of space above, and leaders again to extend other 6 feet. Repeat this annually until the house is filled from the centre Vine, which would be for a house 40 feet long about fourteen years. You would have the benefit of a large amount of young cropping wood each year and two rods heavily cropped.

If desired, the house could be again filled with young wood and fresh rods from the original one in the centre by a similar process of taking them up from the horizontal rod at the bottom wire.

Whichever style is adopted it is important that no crowding of the foliage takes place. The trellis should not be nearer the glass than 16 or 18 inches. At this distance the shoots can be stopped and allowed to remain with their points to the glass until just before the bunches are flowering. They can then be tied down in half the time to their proper places without risk of heeling off. This operation of tying down is generally done too soon in private places. The consequences of precipitation in this matter are very serious, as has more than once been pointed out by experienced cultivators.

As to the best varieties to grow, the Hamburg amongst blacks is still the favourite for early work, but unless for this, or under certain circumstances, it is about the most unprofitable of any, as it will not carry and finish a heavy crop. Madrestfield Court is nearly as early, and when well grown will fetch a much higher price. Gros Colman for a late sort has no equal, and has entirely crushed Lady Downe's out of the market. Alnwick Seedling, where it does, is good, as it will finish a heavy crop; besides, it can be planted 6 inches closer than most of the others. The habit of growth of this variety is the most perfect of all the Grapes I know—medium sized, short jointed, hard well-ripened wood, not so subject to insect attacks as the others. Were it not its bad setting qualities, it would take a different place than it does for market work. Alicante, for an all-round black Grape, owing to the great weight of fruit it can carry and finish, is, I believe, the most profitable of all, and perhaps the most largely grown for market purposes. One of the largest and best Grape growers round London once told me that he could take more money out of a house of Alicante than out of one of equal size filled with Canon Hall Muscat, though the latter were not sold for less than 5s. per lb. Muscat of Alexandria is about the only white worth growing. The object to be aimed at in selecting and growing is big berries and high finish. Flavour is of secondary importance.

I did not intend saying so much about Grapes—though there are a few points in their cultivation which I have not touched of much importance. I cannot help but think that all I have said is but in a sense wasted words, for I would not recommend you to begin growing this fruit for market at its present value, and I am afraid the tendency of prices is still downwards. Tons upon tons of good hothouse Grapes are now sold at an average of 1s. per lb. There is something wrong

certainly when the grower gets say 1s. 6d. per lb. for growing and marketing, and the retailer who hands them over the counter to a customer gets an equal amount for doing so. But to state a remedy is not so easy. The only one I can think of, but which would only be applicable to the smaller grower at a convenient distance from large centres of population, would be for him to take his produce direct to the consumer. The butcher, the baker, the grocer, and the milkman go their daily rounds with their vans, and have a circle of good customers. Why not the fruit grower? At present this is left to a class of hawkers, whose goods, like themselves, are not always inviting. I do not know of two branches of industry that should go better together than dairying and fruit growing. Something similar has often been recommended, and from very high quarters too, but the

FIG. 79.—MR. D. BUCHANAN'S EXHIBIT OF GRAPES AT EDINBURGH SHOW.

mistake in the advice is that farmers have been advised to take to fruit growing, when it should be fruit growers take to dairying. Milk, butter, and eggs are always in request. The customers for these would form a connection for the produce of the garden. The consumer would get his fruit and vegetables fresher and cheaper, and the grower would save the profits of two or three middlemen, which would amount to nearly double what he now gets.

No lecture on fruit growing would be complete without saying something on packing. We have not time to go into particulars. Whatever style of sending fruit to market is adopted, you cannot be too particular in seeing that it is well done, honestly done, and tastefully done. The very best and most reliable labour at your disposal should be employed for this most important department. Grade all fruit thoroughly; it will pay you better sometimes to throw damaged or inferior samples on the rubbish heap than to get a bad name. Once this is got, it is not so easy to get rid of. Your produce will always find a readier and a better market if neatly, tastefully, and honestly packed.

In conclusion, let me say that in treating this subject of profitable fruit growing it has been my endeavour to depart a little from the lines usually followed, in the hope that old truths might be seen in a new light, and that whatever is new or fresh might be the better impressed upon your memory, to stimulate and strengthen independent thought and action, but above all to point out that it is well-directed individual effort that is the mainspring of success. If anything I have said will in any way help you to this end—of making you deeper thinkers and better workers, with an increased interest and love for your work—my object and my labours shall not be in vain.

—D. BUCHANAN.

[We congratulate Mr. Buchanan on the excellence of his lecture. He appears to be one of the few men who can write as well as work, and work as well as write. We last week published an example of the results of Vine border renovation, and have now pleasure in giving a very much reduced photographic representation (fig. 79) of his exhibit of Grapes at the Edinburgh Show. Our correspondent informs us that he will send some notes for our next issue relative to the ventilation of vineries. It will be remembered that several points on this subject were raised by Mr. W. Taylor, of Bath, on page 404.]

WEATHER IN LONDON.—From the time of sending our last issue to the press until Monday morning we had heavy showers each day. The nights, too, were generally wet, and the mornings and evenings cold. On Sunday it was quite dark at intervals, and householders had to light the gas at the time of the midday meal. On Monday and Tuesday it was bright and warm in the sun, but the wind was cold in the shade, while on Wednesday the conditions were similar.

— WEATHER IN THE NORTH.—The weather of the past week has been variable, but decidedly cold throughout. A good deal of rain has fallen, and hail showers have been frequent. The higher hills were, on the morning of the 11th, thickly covered with snow, a heavy fall having taken place in the central and western districts of the county. Frosts have been registered on several nights. On Saturday morning dense hoar frost covered the ground. Early Potatoes were blackened, but the day was fine, as was also Sunday and Monday, with coldish N.E. wind. Tuesday morning was wet, but milder.—B. D., *S. Perthshire*.

— EARLY CABBAGES.—The mild winter has had the effect of bringing the Cabbage crop to maturity at an early date this year, quite full hearts being cut for Easter. Formerly Whitsuntide was considered a very good time to have Cabbages ready to cut, but Ellam's and other early kinds extend the season by some weeks. Earlier than the date named I do not think this vegetable is needed, for there are plenty of other green vegetables available as a rule. Express, a variety I sowed for the first time last autumn, is far behind Ellam's—quite 50 per cent. bolting. Early Offenham and Flower of Spring follow Ellam's very closely, and are really invaluable, either for large or small private gardens or the market grower.—W. S.

— A TRAP FOR THE DEAN—NOT CAUGHT.—Writing in response to a letter from the Editor of the "Vegetarian" asking for his opinion of the views recently expressed by Sir Henry Thompson, the Dean of Rochester says that man is bound by reason, and yet more by religion, to minister so far as he can to the capacity for enjoyment possessed by all animals, and to protect them from cruelty and from all unnecessary pain, but concludes: "Allow me to add that, although I quite agree with you that we eat too much flesh meat and too little of vegetables and fruit, I see no more harm in partaking of lamb and mint sauce now than there was in eating the paschal lamb and bitter herbs by the children of Israel, and I believe that our relish of a haunch of venison is quite as justifiable as it was with Isaac."

— READING GARDENERS' SOCIETY.—The first meeting of the summer season was held on Monday evening last, when the Chairman of the Association, Mr. Turton, presided over a good attendance of members. The subject for discussion was Hardy Flowers, including shrubs and bulbs, which was ably introduced by Mr. Townsend, gardener to Sir William Farrer, Sandhurst Lodge. A discussion followed. An interesting feature of the meeting was the large display of cut flowers contributed by Mr. Turton, Maiden Erlegh Gardens; Mr. W. Smith, gardener to Miss Neild, Greenbank; and Mr. Townsend, the latter exhibiting a splendidly grown Anthurium showing forty-three spathes. A vote of thanks to the lecturer and to those members who had brought the flowers ended a pleasant evening.

— THE QUEEN AND LONDON'S OPEN SPACES.—Mr. G. Shaw-Lefevre, L.C.C., opened, on Saturday afternoon, Charles Square Recreation Ground, Pitfield Street, Hoxton, acquired by the London County Council and the Shoreditch Vestry at a total cost of £1000. Since the year 1604 the ground has been used exclusively by the inhabitants of Charles Square, and as the result of lengthy negotiations it was purchased by the Vestry for £300. Close upon £700 has been expended in laying out the ground by the Metropolitan Public Gardens Association. In declaring the ground open to the public for ever, Mr. Shaw-Lefevre said that within fifteen miles of the centre of London there were 25,000 acres of land maintained for the use of the public, and of that they were indebted to the Queen for 5000 acres in the shape of Royal Parks. As a matter of fact, the public owed much to the generosity of her Majesty in that direction, for she had done more than any of her predecessors to provide beautiful parks and open spaces for the use of the people in the metropolis.

— A GERMAN ROSE SHOW.—We are asked to state that the Gotha Rose Exhibition will take place on July 10th—12th next. All communications to be addressed to the Local Committee at Gotha, Thuringia.

— SHIRLEY GARDENERS' ASSOCIATION.—The monthly meeting of the above Society was held at the Parish Room, Shirley, Southampton, on Monday, when the President presided over a good attendance of the members. Mr. E. H. Bellairs, Wingfield, Christchurch, Hants, gave a most interesting lecture on "Bees and Bee-keeping, and the Relation of Bees to Flowers," which was illustrated with limelight.

— STRAWBERRIES AT BOTLEY.—The following observation came before my notice on a Strawberry plantation near Botley this spring. The plants, particularly those in low lying parts of the field, had gradually dwindled away, the roots having completely decayed, the cause being an excessive application of farmyard manure. The plants were all right as long as the manure remained in an open spongy mass, but when it became thoroughly sodden, and almost impervious to air, the roots were eventually killed owing to the formation of humic acid and the absence of air in the soil due to the sodden manure. It is seldom that an excess of manure is given in field culture, but one invariably finds equally bad results in gardens, not only in Strawberry beds, but likewise in Roses.—J. N.

— PRICES IN THE MARKETS.—Fairly good green peas can now be had at 5d. per lb., but 1 lb. of English makes as full a dish as 2 lbs. of the "foreigners," which are small and comparatively flavourless. French Beans are 6d. a lb. and upwards. Cauliflowers are very cheap, and fresh spring Cabbages are now coming in. Cucumbers and Lettuces are plentiful, and English Tomatoes are 10d. per lb. Rhubarb is extremely cheap. Young Carrots and Turnips are sold at about 4d. the lb., and are very good. Asparagus is cheaper and more abundant. Strawberries are now down in price to 2s. 6d. a basket, holding about eighteen Royal Sovereigns. New Potatoes range from 2d. per lb. There are still satisfactory old ones to be had, but they require to be boiled in their jackets. Spinach can be had at 1½. a lb.

— A TRANSFORMATION SCENE.—The recent warm gentle rains have had their effect on vegetation, with the result that the whole country has assumed a mantle of vivid green. In Kent much of the early fruit blossom is over, and so far as appearances go there are reasons to hope for abundance of Plums, Pears, and Cherries. Apple blossom is later, and the orchards are now a picture. Since the rain came cold winds have disappeared, and the genial intermittent showers and sunshine have altered the appearance of crops in the garden. Early Potatoes are well through the ground and making robust growth, and Peas, which were at a standstill apparently for some time, are now growing apace. Strawberries are coming into bloom, and small fruits generally show signs of heavy crops. Marked progress is apparent everywhere since the welcome rain came, and the warm close atmosphere is conducive to rapid growth.—V. T.

— LATE TULIPS AT LONG DITTON.—Just now the fine collections of late Tulips at the Long Ditton Nurseries are at their best. It is rather difficult to clearly define the time which is assumed to exist between early and late Tulips, for the doubles follow the early singles, the Parrots follow these, then some midseasons fill the gap, and last of all in come the latter late sections, florists' and selfs, many of which keep the garden gay up to the end of May; but few are more beautiful now than are those which, for trade description, are classed as the Darwin section. There are admittedly breeder Tulips, yet the bulk of them seem to be unbreakable, and for that reason they constitute not only reliable, but most beautiful selfs. Very free reference was made to these Tulips in the Journal last year. Those who want beautiful features in their garden borders should have dozens, and plant them in clumps of six bulbs in the early autumn, making the soil good for them, but not unduly rich with manure. Very beautiful are Gipsy Queen, maroon crimson; Cordelia, purple; Joseph Chamberlain, rich crimson; May Queen, soft rosy salmon, a lovely tint; Phyllis, creamy pink, also exquisite; Blushing Bride, red, flushed cream; The Sultan, very dark; The Shah, reddish crimson; and Isabella, evidently sport from Blushing Bride, white, flushed red. These are but a few of the many. Very charming, too, are the Dideiri section, with their long pointed petals and refined aspect in yellow and white, and especially elegans alba, the petals of which are wire edged red. With the cooler weather and abundant moisture prevailing, it may be possible for Messrs. Barr & Sons to show a good collection of Tulips at the Temple on the 25th; but however shown, no method of display can for one moment compare with the beauty seen in masses growing luxuriantly outdoors.—A. D.

— **EXIT THE PAPER-KNIFE.**—I am in entire harmony with "The Missus" in her congratulations *re* the new aspect of the *Journal*, and the abolition of the leaf-cutting guillotine, a real improvement, for which in horticulture the *Journal* is entitled to all credit for its excellent example. Will other papers copy, and go and do likewise?—A.

— **BLACKS IN TOMATOES.**—We grow our Tomatoes in a three-quarter span-roofed pit, running east and west. They are planted along the back and front of the pit; the plants on the back are trained up the wall, and then on to the quarter span of glass. It is on these plants that the fruits are often affected with the black blotches. The blotches have never appeared on or near the flower points, but always on the sides of the fruit. Two very notable facts led me to the conclusion that it is the sun coming on the fruit when in a moist state that begins the mischief. It is only the thin-skinned varieties that are attacked; thicker skinned sorts are free from it, and along the front of the pit, where the plants are trained up about a foot from the glass, and the foliage keeps the sun from the fruit, not one has suffered. By giving more air at nights, and putting a little whitewash on the glass, we got clear of it.—N. N.

— **MEGASEAS.**—It is important that the unlearned should know that Megaseas are no longer existent. They have disappeared from nomenclature absolutely as such. That is at least the botanists' dictum; but they live still as Saxifragas. There is a huge clump of a lovely variety on the rockwork at Long Ditton, and on inquiring its name from Mr. W. Barr, he told me of the new appellation. Instead, therefore, if this truly splendid variety be wanted for Megasea purpurea, Saxifraga ligulata cordifolia purpurea must be asked for. Readers of the *Journal*, of course, like to be up to date with correct naming, but they are a long way in the rear if they have not the superb Saxifrage in their gardens. To get a fine effect, plant three or four pieces, some 12 or 14 inches apart, on holding soil, and in angular fashion, and leave them alone to form a noble clump of leafage and bloom in a year or two.—D.

— **NATIONAL AMATEUR GARDENERS' ASSOCIATION (LIVERPOOL BRANCH.)**—On Thursday evening the monthly meeting of the above branch was held in the Common Hall, Hackins Hey, Liverpool, A. W. Ardran, Esq., presiding over a good attendance. The exhibits were of a high order, especially the cut blooms of Niphetos Rose, staged by Mr. Lunt, those of Catherine Mermet staged by Mr. Hoskyn also being worthy of commendation. Mr. Redfern won with miscellaneous cut flowers, Mr. Cangle with a fine Fern, whilst Messrs. Drake and Lunt divided the special prize, the former with a good Selaginella, and the latter with Lygodium scandens. Other interesting flowers were shown for points. The lecture was given by Mr. R. Pinnington of Roby, who chose for his subject the culture of Lilies in pots. Every point in culture was clearly dealt with, as well as staking, hints on carrying the plants to exhibition, and varieties. The Chairman, in proposing a vote of thanks, said the lecture was more valuable on account of its brevity, therefore more easily understood, and he was sure everyone thoroughly enjoyed it. Several questions were answered by Mr. Pinnington.

— **APPLE CALVILLE ROUGE.**—There has not been shown at any time this year in the flavour competition a handsomer or more beautifully coloured sample of any Apple than was the one of Calville Rouge Mr. Woodward brought up from Barham Court on the 10th inst. Whilst not of high flavour, for none of the varieties shown had real flavour, the flesh was much pleasanter eating than was that of the rather hard-fleshed Herefordshire Pearmain, placed first, whilst as to appearance it was far ahead. Could everyone produce such samples in abundance as Mr. Woodward had of Calville Rouge so late in the season, they would possess almost a fortune, but the variety only succeeds in a warm position; it will not do at all in cold districts or situations. It is a capital Apple for a west wall, where on trees worked on the Paradise stock it finishes admirably. The fruits shown were of good size, conical, beautifully coloured, the flesh soft, and a long way superior to the best in the market, none purchasable at from 5d. to 6d. per lb. I should think as dwarf trees the variety should do well in southern districts on warm sites. Evidently the fruits keep splendidly. I am a little at a loss to understand whether this Apple is the same as some growers term Calville Rouge Précoce. In one trade list I find the variety is classed as a dessert variety, but though called Précoce, is said to keep well till February. No Calville Rouge simply is in that list. In another authoritative list there is Calville Rouge only, there classed as a kitchen variety—ripens from March to May—but there is no mention of the Précoce variety. Are they really identical, and if so, why Précoce? Perhaps Mr. G. Bunyard will help us out of the dilemma. In the R.H.S. lists Calville Rouge Précoce is classed as dessert, but there is no mention of Calville Rouge.—A. D.

— **WAS IT A PUN?**—A week or two since an esteemed friend and amateur gardener mentioned that he had gathered some capital Mushrooms in his garden. I asked whether he had made a bed for them. "Oh, no," he said, "they came up quite spontaneously." Suddenly he realised that he had made an unconscious pun. Henceforth we shall have to understand that Mushrooms on prepared beds come up quite spontaneously.—A.

— **SAINTPAULIA IONANTHA.**—Though this charming little stove plant is now fairly common, it does not appear to be largely grown in private gardens. Belonging to the family of the Gesneriaceæ, and hailing from the Dark Continent, there is sufficient in its neat and attractive appearance to recommend it. The green hairy leaves are not unlike those of Gloxinias, but smaller and less fleshy. The Saintpaulia has been called the hothouse Violet, as its deep blue flowers, produced on stems 3 or 4 inches in length, are not unlike those of the common favourite. If raised from seeds great care is necessary, as the seeds are of diminutive character; but with ordinary attention the plant may be had in bloom continually through a greater part of the year. When in full bloom this is one of the most attractive little plants of recent introduction.—G.

— **EARLY BLOOMING VIOLAS.**—We want many of these hardy bedding plants to bloom much earlier in the spring than does the average number. Looking over a large number of leading varieties planted out in quantity at Long Ditton, I found A. G. Rowberry, the new orange yellow non-veined variety, to be one of the earliest, and giving most brilliant colour. The variety gets rather loose later, but in the spring it is a splendid bedding variety. Very early, compact, and neat, is Dorothy Foster, flowers white tinted mauve. This is a capital bloomer. Of white ground with a heavy blue edge James Cocker is very early and pleasing. The variety is in its markings very true. The best early plum purple is Lady Diana, an improved Cliveden Purple. Archie Grant seems to be the best blue. A very early and compact flower is Marchioness, but it is uncertain, as many plants have white flowers and others have them flaked with blue.—A.

— **RHODODENDRON INDICUM AMGENUM.**—As a pot plant for the greenhouse this, perhaps better known as Azalea amœna, takes a front place, for outside, however, few people appear to be aware of its full value. It is quite hardy in the southern counties, and further north it does well if given a sheltered place. To grow it really well, cuttings should be rooted in August, and kept in a cold frame for the winter. In spring they should be planted in a cold frame, so that in case of very cold nights, either then or in the following winter, a little protection may be given. The following spring the little plants may be put in the nursery border, from which time covering should cease. In three years from cuttings good sized plants may be had. The colour of the flowers is usually better on plants grown outside than on those indoors. From the profusion of flowers annually produced by this plant, the effect of a large bed in full flower may be easily imagined. Such a bed is now to be seen flowering near the "main entrance" at Kew.—W. D.

— **ISLE OF WIGHT.**—The monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Newport on Saturday last. Dr. J. Groves, B.A., J.P., presided over a good attendance of members, who were present to hear Mr. A. Key, M.A., formerly of Wadham College, Oxford, give an experimental lecture on "Plant Foods: Their Detection in Soils and Vegetables." The lecturer spoke of the importance of gardeners being able to analyse their soils and manures, so that they could most economically purchase manures to give a maximum benefit to the soils and crops. After dealing briefly with the more important plant foods, he performed several experiments showing how to ascertain the presence of phosphates in soils and manures, and that seeds and fruits were exceedingly rich in this important plant food. At the close of a most interesting and instructive lecture, to gardeners in particular, a unanimous vote of thanks was accorded Mr. Key. Mr. Mitchell, Barton Board School, kindly provided the apparatus. Several noteworthy exhibits were staged, including a fine spike of Imantophyllum (Clivia) Lord Wolverton with twenty-three blooms, by Mr. G. Nobbs, gardener to her Majesty at Osborne. A plant of Dendrobium densiflorum was staged by Mr. J. J. Linnington, gardener to Dr. Coombes, Newport; and a well-flowered Hydrangea by Mr. J. Nicholas, gardener to Mrs. Gray, Kintore, Sandown. Eleven new members were elected. The first excursion of the season will take place on May 19th, when Appley Towers and St. John's Vicarage, Ryde, will be visited. The fortnightly meeting of the East Cowes Horticultural Society was held on Wednesday last, Mr. G. Groves, C.C., presiding. Mr. A. Saunders, Stanhope Lodge, Cowes, read a paper on "The Cultivation of Carnations."

ROSE SHOW FIXTURES IN 1898.

- June 15th (Wednesday).—York.*
 „ 16th (Thursday).—Colchester and Isle of Wight (Carisbrook).
 „ 23rd (Thursday).—Bath (N.R.S.) and Ryde.
 „ 25th (Saturday).—Windsor.
 „ 28th (Tuesday).—Leeds,* Southampton,† Sutton, and Westminster (R.H.S.).
 „ 29th (Wednesday).—Canterbury, Croydon, and Richmond (Surrey).
 „ 30th (Thursday).—Eltham, Gloucester, and Norwich.
 July 2nd (Saturday).—Crystal Palace (N.R.S.).
 „ 5th (Tuesday).—Harrow and Hereford.
 „ 6th (Wednesday).—Chelmsford, Ealing, Farningham, Hanley,† Hitchin, Redhill (Reigate), and Tunbridge Wells.
 „ 7th (Thursday).—Woodbridge.
 „ 8th (Friday).—Ulverston.
 „ 9th (Saturday).—Manchester.
 „ 12th (Tuesday).—Wolverhampton.*
 „ 13th (Wednesday).—Ipswich, Maidstone, and Newcastle-on-Tyne.*
 „ 14th (Thursday).—Halifax (N.R.S.), Brentwood, Canterbury (Hospital Fund), and Helensburgh.
 „ 16th (Saturday).—New Brighton.
 „ 21st (Thursday).—Sidcup.
 „ 26th (Tuesday).—Tibshelf.
 „ 28th (Thursday).—Bedale.

* Shows lasting three days. † Shows lasting two days.

The next list of fixtures will appear early in June. In the meantime I shall be glad to receive the dates of any Rose shows (or other horticultural exhibitions where Roses form a leading feature) for insertion in that list.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

PRUNING ROSES UNDER GLASS.

MARÉCHAL NIEL and other Roses growing on wires under glass are benefited by pruning immediately the flowering is over for the season. The long growths of the previous year having furnished a crop of blooms may be shortened back to within a foot of their base. This will cause new wood to break strongly and extend to a considerable length in the course of the season. A closer atmosphere and daily syringing will assist the wood to break sooner than dry and arid surroundings. Later in the season all the air and sun possible must be given to perfect the ripening of the wood thus made.—E. D. S.

SOME OF THE NEWER ROSES.

(Concluded from page 393.)

THROUGH the courtesy of Mr. Frank Cant I have had the opportunity of seeing two quite new Teas. One is Madame René Girard. It is not of the exhibition class, but one of those highly coloured varieties which are so much valued for garden purposes and for cutting. The colour is deep coppery yellow, shaded with what the French call capucine. It originated in the well-known establishment of Guillot at Lyons. Another from the same source is Souvenir de J. B. Guillot, and as I have no doubt that the son wished to honour the memory of his father by giving his name to a good flower, I hope it will be a valuable addition. It is described as bright capucine shaded with crimson. It promises to be one of the brightest flowers of this class, and will be valuable for garden decoration.

Much has been said of the manner in which Hybrid Teas were to take the Rose world by storm, but I do not think that evidences of this are as yet forthcoming. Many of those announced are what we should call "wishy washy" in colour, and others very moderate in growth. Of this last I think we must class Charlotte Gillemot, but opinions vary so much upon this point that some have asked the question whether there are not two Roses sent out under this name. It does not seem to have been very much exhibited; perhaps the season of 1898 may decide as to what position it may occupy in future. The two best flowers in this class are of home origin. Mrs. W. J. Grant, raised by Messrs. A. Dickson and Sons, and Clara Watson, sent out by Mr. George Prince, a clear bright Rose, but hardly full enough for general exhibition purposes. Antoine Rivoire, however, of foreign origin, I think promises well, at any rate as a pot plant it is desirable. I saw a beautiful bloom of it on a plant exhibited by Messrs. Paul & Son at the Drill Hall, and I think rosarians ought to look for it during the ensuing exhibition season. It is of a clear flesh colour, of good imbricated form, with yellow shading at the base, and sometimes flushed with carmine.

Passing on to the Hybrid Perpetuals, it is somewhat remarkable, as I have already said, that for the last few years we have had no addition of any great value from abroad, for Comtesse de Ludre and Duc d'Orleans, which are placed in the catalogue of the N.R.S., are both old varieties. Clio, raised by Messrs. W. Paul & Son, and sent out in 1894, is a good Rose of a pale flesh colour with a deeper centre. Lawrence Allen and Bladud, introduced by Messrs. Cooling & Son, are light coloured Roses; but the most numerous additions have been those which have come from

the Newtownards firm, and some of those in the pink shades of colour are certainly amongst our best new Roses.

Mrs. R. S. Sharman Crawford dates back, it is true, to 1894, but it is a very beautiful Rose, which will run Mrs. John Laing rather closely. Helen Keller, sent out in 1895 by Messrs. Dicksons & Sons, is another of the same series in colour, a rosy cerise; the flowers are large, borne on stiff long footstalks, the form is good, and the habit vigorous; it is one of the best Roses sent out by this firm. Tom Wood, a Rose of 1897, therefore, has not been so much seen as some of the others, but apparently it is a very fine Rose, having many good characteristics. It is vigorous in growth, the flowers are large, globular in form, and the petals of great substance, the colour being a cherry red, or, as some would say, a deep pink. The foliage is remarkably fine, and it is stated by its raiser to be nearly mildew proof. There is yet another from the same source which obtained the gold medal of the N.R.S. in 1897, and will doubtless attract considerable attention in the exhibition season, and we may expect it to be shown in good form by the raisers; but as it is not yet in commerce it will hardly be seen in other growers' stands; but I think Ulster, for that is its name, is likely to be a valuable flower.

There are many who will admire the large Pæony shaped flower sent out by Messrs. Paul & Son of Cheshunt, called Rev. Alan Cheales, a pure lake in colour, very free flowering, and it will be especially valuable as a garden Rose. Waltham Standard (W. Paul & Son) I do not recollect to have seen, but Mr. Benjamin Cant, than whom there is no better judge, speaks of it in very high terms of commendation. He describes it as a brilliant carmine shaded with scarlet and violet, with fine stout petals, similar to A. K. Williams. It is a very tempting description, and it is to be hoped it will be shown well this season.

Finally there is Mrs. Frank Cant, a fine hybrid, being a cross between Baroness Rothschild and Madame Gabriel Luizet, partaking very much of the character of the latter flower, very free, very sweet scented, and very vigorous, and I think destined to be a favourite; it received a reward of merit from the R.H.S., and a card of commendation from the National Rose Society at the Crystal Palace. We may look to see it well exhibited this season.—D., *Deal.*

ACHIMENES IN BASKETS.

AN excellent way of producing a charming effect in the conservatory during the summer months is to grow Achimenes in hanging baskets. It is not necessary to enlarge on the beauty and usefulness of the flower itself, as it is known to everybody, and is generally flowered in pots or pans. They are, however, very suitable for furnishing hanging baskets, whether large or small, and the method of procedure is as follows. Shake out the tubers from the soil in which they have been resting, and place them in small shallow boxes or pans, covering with light soil. This should be done in March or April, and where the plants have made a few inches of growth they are now right for transferring to the moss-lined baskets.

When growth protrudes through the soil Achimenes should be disposed close to the glass to keep them sturdy. The bottom and sides of the wire baskets must be covered with close-growing green moss, but this should be done as planting proceeds. First cover the bottom and place in a little soil, then commence with a row of the small plants arranged horizontally round with stems protruding through the wires of the basket. Cover the balls with soil, build up a little more moss round the sides, and follow with another round of plants. Continue in this way till the basket is sufficiently full, and complete by planting on the surface about 2 or 3 inches apart.

The basket should be thoroughly watered through a rose-can and hung in a shady corner of a warm house till the plants commence growing. Then remove to a light airy position in greenhouse or conservatory, and in July, August and September the masses of bloom will amply repay for the trouble taken.—H.

RHODODENDRON FRAGRANTISSIMUM.

MR. R. FILKINS, gardener to R. B. Berens, Esq., Kevington, St. Mary Cray, Kent, included among specimens of Indian Rhododendrons forwarded for inspection a very handsome truss of the beautiful and sweet R. fragrantissimum. Our correspondent observes that these Rhododendrons are "great favourites at Kevington," and of this we are not surprised, seeing how well the specimens sent were grown, as indicated by both foliage and blooms.

We have no clear record of the origin of this handsome Rhododendron. It is supposed to be the result of a cross between the Sikkim species R. Edgworthi and R. ciliatum, and Mr. F. W. Burbidge in his valuable work, "The Propagation and Improvement of Cultivated Plants," states (page 156), "When the lovely and fragrant Rhododendron Edgworthi first bloomed in this country all were eager to see its beauty and perfume transfused into dwarfier and hardier forms. All my efforts failed where I attempted the cross off R. Edgworthi; but while it would

* William Blackwood & Sons, 1877.

not be brought to bear hybrid seed I had no great difficulty in effecting a cross from its pollen on *R. ciliatum* . . . and singularly just as I had obtained it and I sent blooms to lay before the Committee of the Royal Horticultural Society, Messrs. Veitch anticipated me in having a

these *Rhododendrons* prior to the date mentioned ; indeed, we find on page 160 of his work above mentioned, that he was using pollen from his cross on *R. virgatum* in 1864. If he had many pods equally fecund with one he mentions, as containing 324 fine seeds, he raised many seedlings.

FIG. 80.—RHODODENDRON FRAGRANTISSIMUM.

plant of this cross exhibited before that Committee, which is now well known and generally cultivated under the name of Princess Alice."

Mr. Burbidge does not say when he first effected the cross, or when his seedling bloomed, but it is recorded that Messrs. Rollison were awarded a first-class certificate for *Rhododendron fragrantissimum* on April 21st, 1868. The flowers are described as large and beautiful, white faintly stained with rose. Mr. Burbidge was presumably working on

Did some of these from his earlier crosses find their way to Tooting ? Be this as it may, *R. fragrantissimum* as grown by Mr. Filkins, must add greatly to the beauty and sweetness of the conservatory at this period of the year.

The flowers sent were if anything better than represented in the illustration (fig. 80), and as seen pure white, though they are sometimes faintly tinged with rose. When the shrubs get too large for

their positions, or when small plants are required, they can be raised from cuttings, also by grafting and inarching. Cuttings of young shoots when the base close to the old wood is getting firm, inserted in silver sand, kept close and moist in a cool frame for ten days, then plunged in gentle bottom heat, emit roots. When two years clean stemmed seedlings from *R. ponticum* or any other varieties are established in pots, they may be side grafted with scions of desired varieties in August or September, keeping them close, moist, and shaded in a pit, not cutting down the stocks till the union is effected. Saddle grafting also answers in heat in the spring. Inarching may be done at any time during the summer. This is a sure method of increase where stocks can be conveniently arranged for the operation.

HARDY FLOWERS IN OTHER GARDENS.

THOSE who are content to admire their own gardens without seeing those of others lose much. Such is human nature that we are apt to think our own flowers perfect of their kind, and thus fall into the error of resting content with what we have without striving to master more perfectly their wants and ways. We miss, too, the actual observation of new flowers we hear of but have not seen, and are not only prevented from cultivating plants of great beauty, but are often led to grow flowers which we would not have procured had we seen them in bloom. We see happier combinations and better effects than we have thought of, and thus our gardens are less perfect than we can make them.

Not least is the loss of the acquaintanceship of other flower lovers, men and women of various stations in life, but all imbued with the taste for flowers in which we can find a common meeting ground. It is unfortunate that gardeners are, by reason of the pressure of work in spring, prevented from more frequent exercise of the privilege of seeing other places, and thus of acquainting themselves with the rich supply of early flowers; but the owners of gardens might more frequently avail themselves of the opportunity of seeing gardens other than their own in the sweet springtime or in early summer. This much by way of introduction to a few notes on gardens recently seen and the flowers they contain.

First must come the Royal Botanical Gardens of Edinburgh, of the rich collection of plants in which I have before spoken. Mid-April is too early to see these at their best, so much later are flowers there than further south. Thus the reference to this garden must at present be briefer than it deserves, and is rendered still less worthy because of the incessant rain which fell during my stay.

Many changes have been made in those gardens of late, and still others are in progress under the directions of Professor Bayley Balfour. Changes are not always improvements, but the alterations lately made show that the Edinburgh gardens are increasingly becoming more worthy of the Scottish capital, and that they will afford still greater inducements for a visit from those interested in plant life. The hitherto inadequate houses have been improved and largely added to; the arrangement of hardy plants for the study of botany has been remodelled; the rock garden, so prominent and attractive a feature, has been taken in hand; and, in brief, a general overhaul has been, and still is, in progress, which cannot fail to add to the value of the institution. In the beds in front of the houses but few plants were in flower. Several *Doronicums*, such as *caucasicum*, *austriacum*, and *Harpur Crewe*, were in bloom, their golden flowers lighting up the places where they grew despite the general gloom caused by the constant downpour. Here also was observed a neat little *Valerian* coming into bloom, which from its dwarf and neat habit looked as if it might be an acquisition. It was *Valeriana tripteris* (Linnaeus), a European species which I may have seen before, but of which I have no recollection. It is about 9 inches high.

In another bed was *Tulipa Schrenki*, referred by the Kew Index to *T. Gesneriana*. Of dwarf habit, large size, and bright colour, this Tulip is worthy of note. It was too early to see much in flower among the shrubs, but in a short time a magnificent effect would be produced by the *Rhododendrons*. A few were in bloom, and I took a note of a pretty white one of dwarfish habit—*R. anthopogon* (Don)—as of value for small gardens, or in places where dwarf shrubs are sought after. The rock garden has for many years been well known as possessing a very fine collection of Alpine flowers. Its construction has been often criticised, but it is doubtful if many rock gardens more picturesque in effect are as suitable for the welfare of the plants, which is, of course, the principal thing required in such an establishment.

Among the plants in flower were several *Drabas*. It may be said of these that there is much confusion in the nomenclature, and little difference between several of the so-called species. The yellow *Drabas* seen were very effective, and a note was taken of two white species—*D. stellata* and *D. fladnizensis*, as being as good as any of the colour in bloom. *Alyssum Wierzebecki*, a white Madwort, was also in flower. Much prettier, however, was the favourite little Candytuft—*Iberis saxatilis*, whose dwarf, somewhat trailing habit, and heads of white flowers make it of much value. This is the plant I have always known by the above name, and not apparently one mentioned by a contemporary, as on view in the Alpine house at Kew, which differs from the plant usually known as *I. saxatilis*. Is not the Kew plant one known as Little Gem, a variety of *I. sempervirens*?

Nothing gave me more pleasure than several clumps of *Narcissus cyclaminens*. On one of these I saw quite a dozen of the fine yellow-

coloured quaint flowers on healthy plants. *Erythronium grandiflorum* was only in bud. There is a large collection of *Saxifrages*, of many species and forms. *S. Boydi* was very bright with its yellow flowers, and deserving of mention is *S. Salomoni*, a new hybrid Rockfoil, with white flowers, much resembling those of *S. Boydi alba*, but with different foliage. This is, to all appearance, a plant worth growing.

A special feature is the large collection of *Primula* species. Remarkably fine were the trusses on some of the plants of the beautiful pure white *P. viscosa nivalis*. These were finer than any I have seen this season, and formed a delightfully attractive object. The typical *P. viscosa* was also seen with *P. v. decora*, *P. pubescens*, *P. venusta*, *P. obovata*, *P. frondosa*, and many others, including the blue Primrose, now so popular. Even earlier than with us in the south was *Trillium sessile* and *Anemone patens*, the flowers of the latter being of especially good size.

In the pond one could see flowers of the well-known *Aponogeton distachyon*, and by its margin several bog-loving *Primulas* and *Helonias bullata*, the latter being in splendid condition—finer, indeed, than I have seen it anywhere else. At this stage, however, the rain became too much for me, and only time remained before another appointment for a run through the new houses, which are admirably adapted for their purpose, and contain some splendidly grown and attractive plants. Later in the season I hope to visit the Edinburgh Royal Botanical Gardens under more favourable conditions.—S. ARNOTT.

(To be continued.)

AUTUMN VERSUS SPRING DIGGING.

"A MARKET GROWER" seeks to found an argument in connection with this somewhat important matter on insufficient, and indeed an unstable basis. How often has it not happened that the soil has been hard, dry, and difficult to work in the autumn, and easy to dig in the spring. So much depends on the nature of the season, and that is so variable that it is difficult to draw from such data at any one season exact conclusions. Now the land in question is heavy and difficult. I had to work just such land in Middlesex for twenty years, a piece of stiff clay, at times quite heart-breaking to work, and it was my sad experience that, five seasons out of six, if I had portions dug during the winter to accelerate the work of sowing and planting in the spring, that rains would saturate the dug soil, convert it into the consistency of prepared brick clay, then it would bake hard, and sometimes portions would be too hard to be planted at all.

In the majority of cases I found it better to allow the ground to remain untouched till the spring, as then if heavy rains fell during the winter the moisture did not hang in the soil, but passed rapidly through the holes or drains made in it by worms and plant roots. Of course it was needful to put on more labour to get digging done in the spring, but was the lesser evil of the two. It was not needful for me to grow winter crops, but a market gardener must of necessity do so if his labours are to be profitable, and in such case it would be bad gardening to have a large area of ground lying bare or fallow during the winter when it should have been carrying crops of Cabbages, Winter Greens, Broccolis, Spinach, Onions, Turnips, and similar vegetables, or failing these Rye and Tares to cut for horses, or Winter Oats, or indeed any description of green crop to dig or plough in as a green manure.

Of course light porous or sandy soils present few difficulties, and may be dug almost at any time with ease. Taking soils generally, however, and especially where cropped to give the owner a livelihood, a greater consideration inevitably is, under which conditions will the soil give most profit, and be the most productive—by lying entirely fallow, or by carrying a green winter crop? Without doubt the best results come from the latter, that is, if both the teachings of science and experience go for anything. Soil that is lying absolutely uncropped is assumed to be resting and recuperating. That is an exploded theory. Soil gains nothing by resting, but much by recuperating, and that can only be so when it is either carrying a crop to be buried into it as manure, or is recruited by having a dressing of manure or plant food applied.

If, therefore, there be no profit resulting from absolutely "resting" soil, to use a current term, there is no wisdom in allowing it to lie entirely idle, and any description of crop sown on to it in the autumn in time to enable growth to be made prior to the setting in of hard weather is productive of real profit. No doubt the best form of crop is one of Tares; but those of Rye, Oats, Mustard, or Turnips are much better than none. Such a dressing of manure as these catch crops give costs little, and is immediately available for the succeeding crop, as decomposition is rapid, the constituents of the plants being tender and sappy, and not woody, needing much time to become soluble or decomposed, as is the case with dry fibre like straw. All the same, it is surprising how little relatively green manuring of this nature is practised in gardens where it would prove to be profitable.—A. D.

FRENCH BEANS FOR FORCING.—It is probable that few vegetables are more highly appreciated early in the year than French Beans of good quality. Hence any addition that is of decided merit is much appreciated. A new variety raised by Mr. G. Wythes of Syon House promises to be excellent. It is named Wythes' Improved Mohawk, and as shown amongst others by the raiser is very fine. The pods are above average size, freely produced, crisp, and of excellent flavour. It is an advance on the old Mohawk, and is a splendid forcer. The habit of the plant is such as makes it in every respect desirable for culture in pots or boxes.—OBSERVER.

SALE OF ORCHIDS AT WALTON GRANGE.

MESSRS. PROTHEROE & MORRIS completed their sale of Orchids at Walton Grange, Stone, Staffordshire, on Thursday. The following are some examples of the prices realised:—*Cattleya Victoria Reginae*, 44 guineas; *Odontoglossum crispum Alfred*, 34 guineas; *Odontoglossum crispum Golden Queen*, 160 guineas; *Cypripedium Dorothy*, 21 guineas; *Odontoglossum crispum aureum*, 140 guineas; *Odontoglossum Ruckerianum ocellatum*, 50 guineas; *Odontoglossum Wilckeanum nobilior*, 33 guineas; *Odontoglossum meleagris*, 35 guineas; *O. crispum Stevensi*, 110 guineas; *O. Coradinei expansum*, 25 guineas; *Cattleya labiata coerulescens*, 28 guineas; *C. l. Peetersi superba*, 75 guineas; *C. Skinneri alba*, 30 guineas; and *Odontoglossum excellens Thomsoni*, 140 guineas.

ODONTOGLOSSUM CITROSMUM.

It is not often one sees twin spikes on this pretty Orchid, but we have a plant with two from the same lead. Each spike is fully developed, and occurs quite separately from the base, no fusing or fasciation being present. It is one of the most useful Orchids now flowering, and very popular. It is not difficult to grow; few are easier, in fact, but special treatment is necessary to induce it to flower. After the growth is fully made and the bulbs are ripened keep the roots perfectly dry until the tips of the flower spikes can be seen in the young growth. Then give a thorough soaking of water, and the spikes will form and lengthen very rapidly.

It should be grown in a rather higher temperature than the *crispum* and similar sections of the genus, and baskets are preferable to pots on account of the pendant flower racemes. There are several beautiful varieties, the type being white with a yellow crest to the lip, the variety *roseum* having a bright rose lip, and *punctatum* being thickly spotted with rosy purple on each segment. Peat and moss, with plenty of charcoal or potsherds intermixed, will grow it well, and it must be disturbed as little as possible when rebasketing.—H. R. R.

ORCHIDS AT BUSH HILL PARK NURSERIES.

MESSRS. HUGH LOW & Co. have now transferred the last of their collection of Orchids from the familiar nurseries at Clapton to their larger premises at Bush Hill Park, near Enfield, where the plants have more light and purer air. The *Phalenopsis* were removed last February, and they do not appear to have suffered by the journey and change of quarters. The house provided for them has a double span roof, with staging in the centres and at the sides. Large lumps of burnt ballast lay under the stages and by the side of the paths, and this being damped frequently causes a moist atmosphere, which is so necessary to the successful cultivation of these plants. A very distinct form of *P. amabilis* is flowering. It has a beautifully rose-coloured lip, and a band of similar colour in the middle of the petals. It is to be known as *P. a. Kinleside's variety*. *P. leucorrhoda*, *P. Sanderiana*, and *P. Stuartiana* are also in bloom. In the next house *Dendrobiums* are growing vigorously, suspended from the roof over beds of moist leaves and sphagnum moss. At the end of these houses are healthy plants of *Vanda Miss Joachim*, which was illustrated in the Journal on December 9th of last year.

Cypripediums occupy several large houses, in one of which there are many choice species, hybrids, and unflowered seedlings. *Gertrude Hollington* is represented by a large plant in flower, and healthy specimens of *Mastersianum*, *Curtisi*, and *ciliolare* are in bloom, while other houses are filled with *Lawreanum*, *Dayanum*, *Spicerianum*, and others. The *Odontoglossum* houses are each 180 feet in length, and connected at one end by a cool shady corridor, in which is rockwork, adorned with flowering plants of *Ada aurantiaca*, *Oncidium Marshallianum*, *macranthum*, and *undulatum*, with numerous *Odontoglossums* and some *Lycastes*. From the roof are suspended *Sophranites grandiflora*, *Oncidium concolor*, and *Cattleya citrina*, making a charming combination of colour. This portion being rather new, it will be more attractive when the bareness of the stone is relieved with trailing and foliage plants. There is a grand display of *Odontoglossums*, chiefly of varieties of *crispum*, *Pescatorei*, *triumphans*, *cirrhosum*, and *Coradinei*, with a splendid collection of *Dendrobium Jamesianum*.

The structures for *Cattleyas* are on similar lines to the preceding, but are of course warmer. They are effectively furnished with plants of trailing habit, as well as Ferns, Palms, choice *Cattleyas*, *Lælias*,

Lælio-Cattleyas, *Oncidiums*, *Phaius Cooksoni*, large plants of *Calanthe veratrifolia*, *Cymbidium Lowianum*, and *C. l. concolor*. There is a distinct *Cattleya* unnamed, and suggestive of a hybrid between *C. intermedia* and *C. Loddigesi*, with the lip of the former, but much deeper in colour, while the shape resembles the last named. This was shown at the Drill Hall on the 10th inst., and received an award of merit. As there is no dividing wall beneath the stages in this block of houses, there is a circulation of air continually throughout. Two large concrete tanks pass through each division, one being used for rain water, and the other for water pumped up from wells in the nursery, which on account of its hardness is only used for damping the floors and stages. A few *Gaskelliana*, *Schrödera*, *speciosissima*, and *Trianae* are still in bloom, but the wealth of flower is amongst *Mendeli* and *Mossiae*, with *Lælia purpurata*. The plants appear to have grown and matured uncommonly well, especially *Cattleya Mossiae*.

The *Cattleyas* have been grown at Bush Hill Park for some time past, many of them having been established there, and are now flowering for the first time. From these and others of proved merit Messrs. H. Low & Co. will be able to maintain their reputation at the forthcoming Temple Show. Mr. T'Anson has the management of the Orchid department, and to him a word of praise is due for the clean and healthy state of the plants under his care. Other large houses are in course of erection, and there are features of interest in the construction of these which may be worth recording when completed.

In the older portion of the nursery are thousands of Palms, Ferns, New Holland plants, Crotons, and other fine-foliage plants, Azaleas, Pelargoniums, Carnations, pot Roses, and Vines. Beyond the houses are about 40 acres of ground devoted to hardy fruit and Roses, for the culture of which the soil is admirably adapted.—G. W. CUMMINS, Wallington.

AUSTRALIAN MEDICINAL PLANTS.

AUSTRALIA is rich in plants reputed to possess medicinal virtues, although at present only a few have been utilised, and these but to a limited extent. In New South Wales such plants are abundant, many kinds being found in the immediate vicinity of Sydney, especially in the Parramatta district.

One of the most common is the wild Pennyroyal, a decoction of which is largely used as a tonic. A valuable oil can be extracted from it, which may be employed both as a medicine and as a means of imparting a pleasant odour and flavour to other ingredients. Two little plants of the Gentian family, plentiful enough in the spring, have proved highly efficacious in certain stages of dysentery. The common native Raspberry, like other species of *Rubus*, possesses astringent properties which may one day secure it a place in the colonial pharmacopœia, which already includes the native *Sarsaparilla*, although, notwithstanding the latter abounds in the neighbourhood of Sydney, the bulk of the *Sarsaparilla* used by colonial chemists is imported. The country people frequently prepare an agreeable and wholesome tonic from the native plant, which costs nothing save the trouble of collecting it. It is also known by the name of Sweet Tea or Wild Liquorice.

There is also a native Laurel, allied to the *Sassafras* of the pharmacopœia, which possesses medicinal properties as yet but little understood. The native Grape yields a rich crimson jelly, said, when used as a gargle, to be good for sore throat. The native *Veronica* possesses properties in common with the European species, and the leaves are frequently used for making herb tea. Self-heal is plentiful and indigenous, as in Europe; it is bitter and astringent, and occasionally used as a substitute for bark. The leaves, in England, are supposed to be efficacious in healing cuts hence the name. The different species of native Currant possess a powerful acid, capable of being used for flavouring sugar drops, or employed as a substitute for lemon syrup.

The Thorn Apple, Castor-oil Plant, Pimpernel, American Nightshade, Fennel, Wart-wort, and other plants differ very slightly, if at all, from those found in other countries. The Castor-oil Plant not only yields the well-known oil, but the leaves have been successfully employed as a galactopoietic, for remedying the absence of milk in the maternal breast. The Thorn Apple is used as a cure for asthma, the seeds, when expressed and made into an ointment with lard, being good for irritable ulcers, burns, and scalds. The American Nightshade is useful as a purgative; and the Pimpernel is employed in mania and hydrophobia; the juice, when applied to the eye in certain stages of ophthalmia, having the property of cleansing it in a remarkable manner. The medicinal virtues of the various kinds of Eucalypti, or Gum Trees, have become universally recognised, but it is not so generally known that they are shared also by the different species of Tea Tree and Wattle. The flowers of the native *Pittosporum* yield a Jasmine-like scent by distillation; and the Boron and other Rutaceous plants abound in volatile oils.

The foregoing are only a few of the many Australian native plants known to possess medicinal properties, and their luxuriant abundance during the greater portion of the year, combined with the ease with which many species can be cultivated in suitable localities, will, at some future date, give them considerable industrial value.—J. PLUMMER, Sydney, N.S.W.

A PLETHORA OF SLUGS.

THE plethora of gardeners and other subjects have recently been brought prominently to the front by able contributors of the Journal, but apparently no one seems to have found time to advert to the great abundance of slugs, their damage to garden crops, and the best means of combating them. This garden for many years has had an acknowledged partiality for slugs, but why it is so, seems to me difficult to understand. It has been often suggested that lime fresh from the kiln is the one great and unfailing remedy, and I have acted on the suggestion, with a hope that some measure of relief would be afforded. This, however, has not been realised to any appreciable extent, and my faith in the virtues lime possesses in ridding the soil of slugs has been shaken.

The winter being so mild no doubt gave them a chance to carry on their egg production without hindrance. The seed beds suffered in like proportion to that of other portions of the garden, the young plants disappearing as if by magic, lime and soot availing nothing. I am now applying salt in small quantities to the ground where lime has failed, and with this not much better success seems to be forthcoming. Indoors the same trouble has been prevalent, although not to the same extent as outdoors, small slugs or their unhatched eggs being introduced with the new soil, keeping up a succession of losses among tender seedlings and new growth in plants. Night searches by lamplight have had to be instituted and maintained in the latter case to protect plant growth from their ravages.

Mr. Abbey would, I am sure, be able to afford much valuable information with reference to the use of gas lime as a slugicide. I greatly fear that, applied as generally advised in the winter months and left exposed to the weather until its deleterious properties were evaporated, it would not prove equal to the destruction of slugs in the spring. I have found that a light sprinkling of nitrate of soda destroyed a quantity, but this could not be generally employed for the purpose of ridding the ground of slugs. It is strange that, whatever is used, including nitrate, what proves efficacious one season may not do so in another. Of course when there are frequent showers no application can long remain in a useful state as a deterrent to slugs or anything else, and this fact tends to the advantage of the slugs in their egg-production and hatching of the young.

The large earthworm is a great friend of the slug in providing burrows, into which these can find a ready shelter. A frequent use of the Dutch hoe checks their passage somewhat, but nothing one can do is better than deep digging or trenching for destroying slugs. When deeply buried they, like all other animal life deprived of air, must succumb. Close and continuous cropping supports the slug too, for this affords them food at all times without much effort on their part.—W. S., Rood Ashton.

THE VAGARIES OF PRIMROSES.

I WAS much interested by "A. D.'s" notes on this subject, page 405, and now take this opportunity of thanking him for his various jottings. It is apparently a practice of his (and a good one) to make a note of what he finds worthy, and send it to the *Journal of Horticulture*. Seven years ago three roots of the common Primrose (*Primula acaulis*) were planted in my flower garden on the north side of the residence. The following year every one of these plants bore rosy lilac flowers, and so they continued to the present year, when they became much deeper in colour. Not a single "primrose"-coloured flower has been produced by these plants in the six years of their flowering since they were transferred from a hedgebank to the site named. The soil is a calcareous gravelly loam over chalk. They were taken from a clayey loam with chalk at a far greater distance from the surface. The gravelly loam has a red substratum with flints over the chalk, and this, rightly or wrongly, was assumed to be the cause of the changed colour.

The three plants produced a number of seed pods the first year, and many seedlings sprang up the second year. They flowered during the third, and in the bordering or edging of flints on bare soil they all gave rosy lilac flowers, but some of a deeper shade than the parents. On the north of the flower bed, and on the east side also, is a piece of grass 2 feet wide, for it is little use having flowers close to road palings, and on this grass plot the Primroses have found a home. They are seedlings from the same parent plants, and every one bears "primrose" flowers, while those in the soil edging are every one rosy lilac. I attribute this return to the Primrose of the grassy glade to their having a home-like medium, and I am charmed with their rebellion against culture.

I planted Cowslips too, but the three principals are dead. They hate bare soil; but instead of them, and as the result of their influence, I have Oxlips, a cross between the Primrose and the Cowslip, which not unfrequently occurs wild in Britain in company with its two parents, *Primula vulgaris* or common Primrose, and *P. officinalis* or Cowslip, and marks the development of the latter into the Polyanthus (*P. variabilis*), the hybrid in question being a natural one, the *P. variabilis* of Goupil. The flowers are reddish, with deep golden markings, and some of the seedlings are developing the gold-laced type. Not one is an Oxlip proper (*P. elatior*), all being coloured instead of yellow, and the size is that of the Cowslip.

The foregoing may interest "A. D." and others. No manure has been applied to the plants in the seven years, so no change could take place by chemical action. All has been done by Nature and the bees. I cut the grass so as to save the leafage of the Primroses and the Cowslips. Double Daisies planted in the turf have seeded and brought back the common Daisy (*Bellis perennis*). I consider them charming—the bit of

turf with its Primroses, Cowslips, and Daisies under one's eyes—the country in town.

I have also some wild Heartsease (*Viola tricolor*). The flowers get larger year by year, and they are varying much in colour—some selfs and others parti-coloured, some with fringed edges, some also as smooth as show Violas. I only once saw "A. D." about thirty years ago, and then he was preparing frames for Violas, and putting in cuttings at his late brother's place at Shipley, Yorks. The reference to Primroses and Violas has brought the visit to mind. But I must stop, though I may perhaps again venture a few lines on my patch of country in town.—ST. ALBANS.

I COULD have told "A. D." the distinction that exists between a Primrose and a Polyanthus, fifty years ago; but on the same principle that while a mare is a horse a horse is not a mare, so a Polyanthus is a Primrose, but a Primrose is not a Polyanthus. I have seen plants raised from Primrose seed with as many trusses on them as solitary flowers on single stems. What would "A. D." call this? A Primroseanthus, perhaps. The fact that Mr. Arnott gave the variety "John Wilkinson" such a high character after the plant had travelled two journeys by parcels post of over 300 miles each perfectly justifies me in making what "A. D." calls a "fuss" about it. Every reader knows that a pin-eyed flower is just as good for garden decoration as a flower with a thrum eye. There is another eye I like less than the pin eye; happily it is not in the flowers—it is a prejudiced eye. Sometimes it is found in those who worship at "Flora's shrine." "A. D." seems to have an eye of his own—a sharp pen eye—but he will not deter me from sending notes of anything I may think will be of interest or service to the readers of the Journal. I have received much benefit myself from such notes, and often from "A. D.'s" pen. I would have liked very much indeed to have seen the grand show of Polyanthus referred to at Farnham, but there is just a possibility, as the Scotchman said, that the variety "John Wilkinson" is as good, or it might even be better, than any of them. Merit is not always found in multitudes.—N. N.

CYCLOBOTHA AMÆNA.

THE delicate beauty of many of the Cyclobottha and of the Calochorti, to which they are nearly allied, is well known, and yet they do not receive a great amount of attention. Old varieties are frequently shown at the Drill Hall, especially by Messrs. R. Wallace & Co., while new ones are occasionally sent by this firm and others. They invariably come in for a large share of admiration, and though their popularity is doubtless on the increase, they deserve still further attention. A charming form is *C. amœna* (fig. 81) of which the flowers are of a pale rosy mauve shade, with three dark blotches in the centre of each. The sepals and petals are rather long and narrow, the latter being twisted, and they are hirsute. The anthers are white, making the flower more conspicuous.

HORTICULTURAL SHOWS.

NATIONAL TULIP SOCIETY.—MAY 11TH.

IT was most unfortunate that the date of the show in the Royal Botanic Gardens was fixed so early, and though an attempt at postponement was made it was found to be impracticable. As the day was quite a week too soon for Tulip blooms several members of the Society were unable to stage any flowers, Mr. J. T. Bennett-Poë and Mr. G. Edom being unrepresented, whilst Mr. Bentley could only bring very few, and found himself unable to compete for the championship in Class A; no fault, however, could be found with those he exhibited. Messrs. Barr and Son showed blooms of first-rate quality, but unfortunately several were badly damaged by hailstones. In Class A, for instance, their flowers were clearly of the best quality; but both Messrs. Chater and Hall were able to stage fresh and undamaged specimens.

The season has been rather a cruel one for the Tulip, and the death-dealing hailstorm too often in evidence. As a result the glory and brightness of the bloom were much diminished. Feathered flowers were very scarce, and of only medium quality. Industry, a fine rose, though very young, shown by Messrs. Barr; and a byblœmen, John Linton, shown by Mr. Chater, very much like Adonis, but we are informed of different habit, were very conspicuous. The example of Samuel Barlow, as seen in Mr. Chater's stand of twelve, Class A, was very rich and brilliant, the marking being fine, the feathering especially so, and quite deserved the premier prize, even though a very fine Paxton and a good Talisman were in close competition. It is seldom indeed that Sir Joseph Paxton can be dethroned from premier honours, but Samuel Barlow is worthy of the succession; its cup is better, its petal much broader and of better shape, though it is rather of the red and orange colours, than the much desired black and yellow that Paxton so nearly approaches. We fear, however, that whilst we have hundreds of Paxtons, we may only have units of Barlows. Paxton will still be unique for quality and quantity combined. Goldfinder (originally from the late Mr. Barlow's collection), a beautiful flower, exhibited by Messrs. Barr and Sons in Class E, was awarded premier honours for breeders.

Class A.—Twelve dissimilar Tulips, rectified, two feathered and two flamed of each class. First prize, Mr. A. Chater, Cambridge, with

bybloemens Duchess of Sutherland and Mrs. Jackson flamed, John Linton and Guido feathered; roses: Sarah Headley and Glory of Stapleford flamed, Sarah Headley and Modesty feathered; bizarres: Samuel Barlow (premier flamed) and Orion flamed, Masterpiece and Richard Headley feathered. Second prize, Mr. A. D. Hall, Wye, with bybloemens Coningsby Castle and Duchess of Sutherland flamed, Adonis and Bessie feathered; roses: Aglaia and Annie McGregor flamed, Miss Edwards and Count feathered; bizarres: Richard Yates and Sir Joseph Paxton flamed, Duke of Devonshire and Masterpiece feathered. Third prize, Mr. C. W. Needham, Royton, Manchester, with bybloemens Duchess of Sutherland and Talisman flamed, Nellie Hughes and Universe feathered; roses: Aglaia and Mabel flamed, Modesty and Lloyd's 214 (a new break) feathered; bizarres: Sir Joseph Paxton and Dr. Hardy flamed, Sir Joseph Paxton and Lord Lilford feathered. Fourth, Messrs. Barr & Sons, Covent Garden, with bybloemen Amazon and Duchess of Sutherland flamed, Mrs. Jackson and Friar Tuck feathered; roses: Aglaia and Mabel flamed, Industry (premier feathered) and Lady Grosvenor feathered; bizarres: Sir Joseph Paxton and Samuel Barlow flamed, Samuel Barlow and Lord Lilford feathered.

Class B.—Six dissimilar Tulips, one feathered and one flamed in each class. First prize, Mr. J. W. Bentley, Middleton, Manchester, with Adonis, Annie McGregor, and Lord Stanley flamed; Bessie, Count, and Wm. Wilson feathered. Second, Mr. A. Chater with Duchess of Sutherland, Sarah Headley, and Dr. Hutcheon flamed; John Linton, Modesty, and Masterpiece feathered. Third, Mr. C. W. Needham with Duchess of Sutherland, Aglaia, and Dr. Hardy flamed; Sarah, Modesty, and Masterpiece feathered.

Class E.—Three flamed Tulips. First, Mr. Bentley, with Universe, Mabel, and Lord Stanley. Second, Mr. Needham, with Mrs. Jackson, Mabel, and Samuel Barlow. Third, Mr. Chater, with Duchess of Sutherland, Annie McGregor, and Sir Jos. Paxton.

Class F.—Six breeder Tulips, two of each section. First, Mr. A. D. Hall, with bybloemens Glory of Stakehill and Lloyd's 200; roses, Mabel and Annie McGregor; bizarres, John Heap and Excelsior. Second, Messrs. Barr & Sons, with Miss Foster and Talisman, bybloemen; Lady Grosvenor and Mabel, roses; Samuel Barlow and Goldfinder, bizarres. Third, Mr. J. W. Bentley, with Janette and Adonis, bybloemens; Queen of England and Mabel, roses; Excelsior and Storer's Seedling, bizarres.

Class G.—Three breeder Tulips, one of each section. First, Mr. Bentley, with Glory of Stakehill, Mabel, and Storer's Seedling. Second, Mr. Needham, with Adonis, Annie McGregor, and Wm. Lea.

Class H.—The Samuel Barlow prizes for pairs of Tulips, one feathered and one flamed, of any class. First, Mr. Bentley, with Duke of Devonshire feathered, San Jose flamed. Second, Mr. A. D. Hall, with Count feathered, and Sir Joseph Paxton flamed.

Class I.—Premier flamed Tulip, Mr. Chater for his Samuel Barlow, a noble bloom in class A. Premier feathered Tulip, Messrs. Barr & Sons, for Industry, an excellent clean feather, exhibited in class A. Premier breeder Tulip, Messrs. Barr & Sons, for Goldfinder, exhibited in class F, a very bright, attractive flower.

Class J.—Collections of English Florists' Tulips. The gold medal was awarded to Messrs. Barr & Sons for their fine and extensive exhibit.

The large silver medal of the Royal Botanic Society was awarded to Messrs. Barr & Sons for their magnificent group of decorative Tulips, Darwin and others, exhibited in the large tent.

The afternoon was sunny, but not warm, or the Tulips might have shown to better advantage.—C. W. N.

ALEXANDRA PALACE.—MAY 18TH, 19TH AND 20TH.

THE first flower show since the re-opening of the Alexandra Palace cannot be recorded as a great success. No doubt the date fixed was somewhat unsuitable, owing to the close proximity of the Temple and Manchester shows. At the same time there should be sufficient material in the immediate neighbourhood to supply a better competition. It is an ideal place for a floral exhibition, the hall being very spacious and well lighted. On this occasion the competition was very weak, though the individual exhibits were in every way satisfactory. It is to be hoped future exhibitions will be more largely patronised, both by the trade and other growers.

Messrs. J. Peed & Sons, West Norwood, were awarded the first prize for a group of flowering and foliage plants, arranged in circular form. It was composed of Palms, Dracænas, Caladiums, Ericas, Begonias, Ferns, and Grasses. The plants were excellent, though a little more artistic arrangement appeared wanting. Mr. Geo. Cragg, gardener to W. C. Walker, Esq., Winchmore Hill, was placed first for a group of Orchids tastefully arranged with Palms, Ferns, and Caladiums. The Orchids were composed chiefly of Cypripediums, Cattleyas Schröderæ and Skinneri, Odontoglossums crispum and Andersonianum, Oncidium and Dendrobiums, the whole forming a very attractive exhibit.

Messrs. J. Peed & Sons were the only exhibitors in a class for nine foliage plants with medium specimens. The best were Kentia Belmoreana, Latania borbonica, Phormium tenax, Kentia Fosteriana, Dracæna Gladstonei, Croton Weismanni, and Dracæna Lindenii. Messrs. Paul & Sons, Cheshunt, secured premier honours in the large class for hardy flowers, making an extensive exhibit. The bunches of Azalea mollis in their various hues were very attractive. Rhododendrons were also a special feature. Parrot Tulips, Pæonies, Adonis vernalis, Geums, Megaseas, and Scillas all contributed to make up the display.

Mr. Amos Perry, Winchmore Hill, was awarded first prize for a collection of hardy flowers. The chief were Geum Heldreichi, Trollium americanus, Irises in variety, Lilliums davuricum and Harrisii, Tulips of

the gesneriana type, and Phloxes. The whole made a very pleasing display. Mr. Geo. Cragg was placed first for twenty-four bunches of cut flowers. There were Cannas, Lælia grandis teubrosa, Dendrobiums, Cattleya Mendeli, and Cymbidium Lowianum, while the hardy kinds were Cytisus albus, Trollius europæus, Doronicum Harper Crewe, Tulip Golden Eagle, and Irises.

The Canterbury Roses were the only representatives of the queen of flowers. Mr. Geo. Mount was deservedly awarded the first prize for twenty-four blooms with very fresh specimens; Mrs. John Laing, Bridesmaid, La France, Catherine Mermet, Caroline Testout, Gustave Piganeau, and Mrs. W. J. Grant were the best flowers. The same exhibitor was again placed first in the class for twelve blooms with equally fine flowers. Messrs. Perkins & Sons, Coventry, gained premier

FIG. 81.—CYCLOBOTRYA AMENA.

honours for bouquets, executed in their well known style. Mr. H. O. Garford, Stoke Newington, was second; and Mr. L. H. Calcutt, Stoke Newington, third.

Messrs. Wm. Cutbush & Son, Highgate, had a very fine group of foliage and flowering plants. The former consisted of Palms in variety, Bambusas, Ferns, and Grasses. The flowering plants were represented by excellent Carnations, including Princess of Wales and Princess May; Azaleas and Ericas, and a variety of spring flowering plants (gold medal). Mr. Thos. S. Ware, Tottenham, staged a large collection of hardy plants and flowers, composed of Tulips, Irises, Narcissi, Trolliums, and Doronicums amongst others. The plants were represented by Ranunculus speciosus, Geum Heldreichi, Orchis fusca, Ramondia pyrenaica, Primula involucrata, and Epimedium macranthum (gold medal).

Mr. S. Mortimer, Rowledge, Farnham, staged a good exhibit of twenty boxes of Cucumbers and Tomatoes. Sutton's A1, Rochford Market, Sutton's Peerless, and Improved Telegraph were most notable in the former section, while the latter was represented by well-grown and coloured fruits of Mitchell's Hybrid, Abundance, and Improved Conqueror (gold medal). Messrs. Wood & Sons, Wood Green, had one of their well-known displays of horticultural sundries, composed of a variety of things required daily in the garden.

A CALL AT WILLIAMS'.

It is probably very rare to find a horticulturist go to Holloway or its immediate neighbourhood without making a call at the Victoria and Paradise Nurseries of Messrs. B. S. Williams & Son, and it is certain that something will be found to repay the visit. It will not be long ere, to see the whole of the firm's stock, the journey will have to be extended as far as Finchley, where several acres of land have been acquired, as was briefly noted in the last issue of the Journal. The advantages of such a secondary establishment to a nursery business will be apparent to all who are conversant with the difficulties that have to be surmounted when growing plants in London. It may be said that Holloway is blessed with a pure atmosphere, but such is not the case, for smoke and fogs are far too abundant, and there will doubtless be quite sufficient at Finchley, where, as a rule, the air is purer and more bracing than it is closer to the metropolis.

However, much cannot yet be said relative to the new place, save to surmise that it will not be a great time before it is as well stocked as the old home at the foot of Highgate Hill. There may be seen thousands of flowering plants, equally large numbers of those grown for their foliage, while it is needless to add that Orchids are seen on every side. Vast quantities of choice flowers, Ferns, Palms, and others, are required for one purpose alone—namely, the maintenance of a constant supply to the floral store in Piccadilly, where may always be seen something of more than ordinary beauty, and displayed in a most artistic fashion. Quality of flower or leafage is of paramount importance here, and it will be for its service that the Finchley nursery will be of the utmost value. The firm's skill in the making of floral devices is widely known, while the excellence of the flowers and foliage is of the highest.

Though there are not a great many houses at Holloway it is needless to say that the most has been made of the ground at disposal, while the structures themselves are full to repletion. The stock is of all kinds and varieties, and the major portion of the plants are in excellent health. The number of Palms in variety is enormous, and the diversity of size is most marked, some being scarcely more than seedlings, whereas others tower high above the head in the great conservatory at the main entrance. Enumeration of varieties is not desirable, as all are grown that are suitable for any phase of decoration. Crotons, too, are a great feature, and it is little short of surprising to see the richness and intensity of the colour development when we think of the smoky glass that surmounts them. Other coloured foliage plants are of the same high order, proving that the defects in the climatal conditions are made up for by general excellence of cultivation in every stage of the plant's growth.

Very noticeable as the several houses were traversed were the finer foliaged Aralias, and it was evident that the beauty and elegance of these plants were appreciated. Ferns occupied a considerable amount of space, as did Caladiums in various stages of growth. One might further enlarge upon the foliage plants, but mention must be made of the forms of Pitcher Plants that prove of so much interest to visitors. The most largely grown are the Nepenthes, with their pitchers at the extremities of the leaves. The varieties were numerous, and the plants were in capital condition. Then the North American Pitchers, commonly called Side Saddle Flowers, from the more or less fanciful resemblance of the flower to a lady's saddle, and botanically known as *Sarracenias*. These having been duly admired, the almost recumbent pitchers of *Cephalotus follicularis* were compared with those of the large *Nepenthes*, and the difference of habit noted by our guide, Mr. Glendenning. Just another carnivorous plant was observed—namely, *Dionæa muscipula*, whose peculiar leaves proved almost fascinating to some ladies who were visiting the nursery.

Turning now to the flowering plants we find ourselves confronted with a very long list, including Indian and mollis Azaleas, excellent Cannas, Carnations, Lilacs, Lily of the Valley, splendid Clivias with their handsome leaves and great globular heads of flowers, and which are here grown to such perfection; Amaryllises, past their best, but still bearing traces of a former greatness, and Anthuriums with hundreds of their brilliant scarlet and other coloured spathes, with a profusion of Orchids. In order to reserve space for a few of the most noteworthy of the latter no more plants will be named, for readers will know their names when it is said that all seasonable ones were there in abundance. The collection of Orchids at these nurseries is probably larger than many people suppose, and it embraces all the popular kinds in bulk, with others in lesser numbers according to their importance. House after house contained nothing but Orchids, some in flower, others just showing, with still more past their zenith; but each and every one in good health and condition.

Odontoglossums were making a rich display, and several forms of crispum were observed that were distinctly above average merit. *O. Ruckerianum*, *O. Harryanum*, *O. polyanthum*, and *O. excellens* were represented, as well as *O. cirrhosum*, *O. luteo-purpureum*, and *O. triumphans*. Cattleyas were not quite at their best, but forms of *Mendeli* and *Lawrenceana* were observed, with abundant promise on the other plants. Forms of *Lælia purpurata* were fairly numerous, some being of great merit, while *Cymbidiums*, *Vandas*, *Ada aurantiaca*, *Oncidiums*, *Phalænopsis*, *Dendrobiums*, and *Lycastes* were numerous and good. But of all the Orchids the *Cypripediums* were making the best display, and what with species, hybrids, and varieties, were well nigh endless. Almost all of those that flower at this period of the year, such as *Leeanum*, *Gertrude Hollington*, *grande*, *Charlesworthi*, and *Sedeni* were seen and admired for their handsome flowers and their rude health. These there were and others, but those readers who would know more of the occupants of the Victoria and Paradise Nurseries should wend their way to Holloway as early as they can, and will, like us, be more than satisfied with what they see.—P. J. R.

THE YOUNG GARDENERS' DOMAIN.

FAILURE, EXPERIMENT, SUCCESS.

THE defective, irregular break of the young rods in our early and midseason vineries this year proved to be a source of great anxiety and disappointment. At the time of starting they were tied in the orthodox style generally advocated and adopted—viz., by depressing the ends to form a slight curve. This method, it is affirmed, retards the rush of sap to the upper part of the rods, and assists in distributing it evenly from base to apex. But does it produce the desired effect? After studiously observing the results of this method (and it was my privilege to receive my elementary gardening education at a place where two score pot Vines were annually grown, besides four established vineries), I reply in the negative.

The young rods in question made a most satisfactory break on the outside of the curve, but the inside, or under eyes, scarcely made a start, and are at the present moment a great eyesore. The old rods in the same houses were suspended longitudinally, and made a most desirable break.

This observation, after some thought, led to an experiment. When starting the late vinery, instead of tying the young rods down in the orthodox style, they were suspended the same as the old rods. They produced a result exceeding all anticipation, breaking evenly the full length of the rods, thus practically proving the fallacy of the tying down practice.

I have frequently heard complaints about the irregular break of young Vine rods, so perhaps these few notes may prove of assistance. May I be allowed to ask those who still consider it necessary to adhere to the old practice of tying down—Would it not somewhat obviate the irregularity of the break by bringing the ends over *vice versa* after a few days' start, thus giving the same treatment to both sides of the rods? Perhaps some experienced cultivators will enlighten our minds on the subject.—VINIFERA.

WALLFLOWERS.

WALLFLOWERS are largely grown for spring bedding, and when bushy plants are to be had in the autumn a grand display of bloom may be expected. Many failures can be attributed to late sowing, leaving the seedlings to become drawn and weakly in the seed beds, or indifferent cultivation afterwards. When sown late they do not make such free growth or mature it, and consequently do not flower so freely.

Seeds should be sown about the middle of May, on a border which has an open sunny aspect; they are partial at this stage to a rather poor soil, well worked and gritty. When 2 inches high transplant them into rows 6 inches asunder, and 3 inches apart in the rows. In three weeks or a month the plants should be again transplanted, lifting every other row, and each alternate plant from the rows that remain, care being taken to keep as much soil adhering to the roots as possible.

The plants which are removed should be placed a foot apart each way, which gives them ample room to develop. If the weather is dry a thorough watering is necessary, and weekly waterings afterwards should hot weather prevail. Occasionally stirring the soil with a hoe between the plants is beneficial to them. Under the foregoing treatment they will make "stocky" plants of good size for planting in autumn, where they are to flower. Wallflowers are quite hardy, but are liable to be injured if frosts follow after heavy rains. The soil I have found to suit them best is a well-drained and deeply worked sandy loam.—NIL DESPERANDUM.

FORCING ROSES.

So universally appreciated is this queen of flowers that it would be difficult to prolong its season of flowering to excess. Roses may be had in abundance by the middle of March, or earlier if desired, by the aid of artificial heat, and thus a supply may be kept up until outdoor flowers are plentiful. The house having been thrown wide open during the autumn, and the trees exposed to the elements, a start may be made to prune the Roses preparatory for forcing. In pruning, the operator must be guided by common sense combined with a knowledge of the several varieties. In the case of climbing Roses remove old and exhausted wood, and retain a fair number of firm young growths, these being laid in at full length. Dwarfs are pruned according to their strength, the weaker ones being pruned the harder to insure a strong break, and *vice versa*, the object being to secure healthy young wood in abundance; it is recommended, however, never to prune Roses too hard that are to be forced early. Should the borders require renovating, remove a portion of the surface soil and give a liberal dressing of cow manure and heavy loam, the whole to be thoroughly settled by a soaking of water.

Roses in pots require a thorough overhauling, and in most cases repotting and relabelling. The balls of soil being fairly moist, turn the plant out of the pot, and with a pointed stick remove the crocks and part of the old soil, taking care not to injure the roots. If it is desired to replace them into the same size pot, a number of the older, and all injured roots may be removed, always making a clean cut. When this is accomplished, proceed to repot in clean, properly crocked pots, using a compost of heavy loam, with a fair proportion of cow manure and $\frac{1}{2}$ -inch bones. Place the compost into the pot in small quantities, making all thoroughly firm as the work proceeds. Water sparingly at first, until the roots take hold of the new compost, after which time abundance will be required.

Provided the work of pruning, top-dressing, and tying is finished by the end of the old year (which in all cases it should be for early forcing purposes), the house may be closed at once, maintaining a night temperature of 45° for the first few weeks, with a corresponding rise as the year advances and the sun gains power. After the first fortnight admit a little

air constantly if the weather permits, but avoid cold draughts, which are almost fatal to success. They bring in their wake aphides and the much-dreaded mildew, which, if once allowed to get a footing, is very difficult to eradicate. Always take the precaution, therefore, to allow no water to remain on the foliage after nightfall. As a remedy against mildew sulphur may be dusted on the affected parts as soon as detected; for aphides, an occasional use of XL All vaporiser will suffice to keep them in check. One more enemy of the Rose which I must not omit to mention is the Rose maggot, which makes its appearance simultaneously with the flower buds, and if not checked, will soon make short work of a whole crop of flowers. The best remedy is hand-picking, and a diligent search twice a week during the early part of the season will keep the pest at bay.

The syringe can be used lightly on bright mornings until the flowers open, damping the available surfaces being sufficient on dull sunless days. As growth advances, thorough soakings with tepid water will be required, and assistance in the form of liquid manure will greatly enhance both the size and colour of flowers and foliage. If large blooms be required, remove all buds except the centre one at an early stage, this being done early in the day when the growths are brittle in precisely the same manner in which Chrysanthemum buds are taken. As soon as a flower has passed its best it must be removed, as nothing tends more to shorten the season of flowering than leaving old flower stems on the plants. This rule may be applied to all flowers with equal force.

So many varieties of diversified colour and good habit are now offered for sale by our leading Rose growers that it would be unwise for me to enumerate any varieties here. Suffice it to say that if the selection is left to the nurserymen they can in most cases be relied upon to supply a succession of useful varieties at a reasonable price. From the fact that we have during the last few weeks cut many hundreds of useful Roses for house and personal decoration it may be inferred that their culture is understood, and the details given are quite trustworthy.—T. P.

HARDY FRUIT GARDEN.

Apricots, Peaches, and Nectarines.—*Thinning Fruit.*—A good set of fruit necessitates a considerable amount of thinning, which should be commenced early. The fruits of Apricots will be the first to require attention. Commence with the removal of ill-placed fruit. Thin-out the smallest of the remaining fruits at intervals, finally leaving the best and most prominent at a distance of 4 inches apart. Moorpark Apricots and similarly fine varieties may be left 6 inches asunder. Peaches may be left 10 and Nectarines about 8 inches apart. Vigorous trees, however, will carry a larger crop than weak trees. This must be borne in mind when finally apportioning the fruit. Any fruits which turn yellow or fail to swell freely are useless, and there are numbers which it is not desirable should be retained, owing to their unsuitable position behind branches or close to wires. These can be clipped off as soon as possible.

Watering.—Should there be any probability of the soil about the roots being dry, it will be desirable to apply a copious soaking of water. Trees in foliage and swelling fruit demand constant and regular supplies of moisture for the roots, and as the crop advances additional nourishment, which may be afforded by liquid manure.

Syringing.—A good syringing of the foliage towards the close of warm days is of material assistance in maintaining the trees clean, disturbing insects, and preventing their multiplication. If green and black aphides make their appearance, in spite of daily vigorous syringing with clear water or through neglecting to syringe at all, applications of soapy water, 2 ozs. to the gallon, must be given. Strong insecticides are effective destroyers of insects, but they are also liable to damage the young fruits, hence their employment is not so desirable early in the season. The advertised mixtures upon the whole are good, and save time in preparation, but they ought not to be used stronger than advised by the vendors.

Thinning and Regulating Shoots.—There will probably be some surplus shoots requiring removal or thinning out to properly furnish the trees and prevent overcrowding. It is, therefore, essential to make examination at intervals, cutting out any crowded growths or shoots unsuitably placed for laying in, as such may be overlooked in the course of disbudding. This should be considered supplementary to disbudding, and is better carried out now, than allowing known useless shoots to occupy space and crowd the trees for a whole season to be eventually removed.

As a rule each bearing shoot of Peaches and Nectarines, also many of those of Apricots, require a young vigorous growth at the base to be trained in as a successional shoot for the following year. These must be reserved now, if not fixed upon at the earlier disbudding. One growth above the fruit must also be encouraged. The basal shoot is best if left on the upper side, carrying this out systematically if possible. Its adoption will certainly prevent crowding, and render the training easier.

Pears.—The fruit on cordons, pyramids, and small bush trees may be obtained finer if thinning is practised. Gradually reduce the fruit to two

upon each spur. A vigorous syringing is a good method of clearing away dead petals and imperfectly fertilised fruits failing to swell.

Plums.—A preliminary thinning of the bunches of fruit may be carried out with Plums on walls, the trees having set a fair quantity of fruit. The final thinning should be deferred until the fruits have stoned. Syringe the trees in warm weather as an aid to cleanliness, but the points of shoots attacked with aphids ought to be dipped in an insecticide or dusted with tobacco powder. The removal of superfluous shoots should still be carried on. Some may be required to lay-in for extension or furnishing, but the lateral or foreright shoots need shortening to three full-sized leaves.

Raspberries.—Hoe down small weeds between the rows, and fork or pull up strong rooted weeds. Superfluous suckers, while yet comparatively small, should be thinned out, so as to leave plenty of space for those which are to be permanently retained. Suckers frequently spring up freely at a distance from the stools. The strongest, if carefully lifted and replanted on good ground, will soon be established. Whether required for planting or not, all such suckers ought to be forked up, not hoed off close to the surface, as they will grow again. On light soils, after hoeing, a mulching of manure may be given.

General Hoeing Fruit Quarters.—Weeds are sure to grow among fruit trees and bushes at this season; therefore, to keep them down and maintain the soil clean, the Dutch hoe should be run over the ground on dry sunny days.

Mulching Gooseberries and Currants.—As Gooseberries and Currants are now swelling their crops of fruit, an application of decomposed manure placed over the roots, and water or liquid manure given, will assist largely in affording the extra nourishment required for perfecting a crop.

FRUIT FORCING.

Figs.—*Early Forced Trees in Pots.*—When the first crop on the very early varieties is gathered return to the treatment applicable to trees swelling their crops. If red spider has gained a footing thoroughly cleanse the trees with some approved mixture. Syringe the trees forcibly on fine evenings until new growth is being made freely, and in ordinary routine twice a day—in the morning and early afternoon. Where the second crop is thickly set thin liberally, leaving the fruits nearest the base of the shoots, and do not overtax the trees. Expose the ripening fruits as much as possible, and increase the ventilation. Stop the shoots and thin where crowded, for vigorous sturdy shoots produce the finest Figs.

Planted-out Trees.—The earliest started trees have the fruit approaching ripeness, and must not be wetted, maintaining atmospheric moisture by keeping the mulching, walls, and paths properly moistened. Moisture can be prevented from condensing on the fruit by keeping a steady circulation of air with gentle fire heat. Care must be taken to afford plentiful supplies of tepid liquid manure to the roots. Allow the leading shoots now to extend, unless unduly vigorous, until they reach the extremity of the trellis, then stop them.

Late Houses.—Though Figs are grown very successfully in unheated houses, producing one crop, which affords an acceptable supply of fruit in August and September, they require in some localities a genial warmth, especially the late varieties, such as Negro Largo, to ripen properly. The trees must have copious supplies of water, and be syringed twice a day. In cloudy weather, however, the afternoon syringing should be dispensed with. The young growths in these structures must be trained a good distance apart, every shoot having full exposure to light and air, so as to insure sturdy fruitful wood.

Vines.—*Early Forced.*—Where the Grapes are ripe, fire heat will only be necessary to keep the temperature at about 60° at night, ventilating freely by day. Black Hamburgs will need slight shade, and it will also prevent amber-coloured Grapes, such as Buckland Sweetwater, assuming a brownish hue. Damp the house occasionally, not allowing moisture to be condensed on the berries, but dissipate it by early ventilation. A certain amount of air moisture is necessary for the foliage, and it will not injure the Grapes, provided the atmosphere is not stagnant. A moderate extent of lateral growth should be encouraged, as it tends to keep the roots active, and to prevent the premature ripening of the foliage, which must be kept clean and healthy as long as possible.

Vines Started at the New Year.—The Grapes are colouring, and need a moderate amount of air moisture, damping the house two or three times a day until the colouring approaches completion, when a drier atmosphere will be advisable. Free ventilation should be afforded, having a little at the top of the house constantly; a circulation of warm air contributes to good finish and quality. Moisture at the roots must be furnished thoroughly; one good soaking of tepid liquid manure when the Grapes change colour, and a mulch of partially decayed manure, will generally suffice until the crops are ripe. Keep the night temperature at 65°, a little more on warm and a few degrees less on cold nights, 70° to 75° by day, 80° to 90° with sun heat, and full ventilation, closing between these numbers all but a small space at the top of the house.

Succession Houses.—The sun is an important factor in keeping down the coal bill. There is nothing like opening the ventilators early in the morning, admitting air in a safe quantity to pass through the house. It causes moisture to disappear, allows the foliage and fruit to warm equally with the atmosphere, preventing scorching, while elaboration begins early, and is continued through the day. By closing early the crops are accelerated in swelling, provided there is a due supply of atmospheric moisture, which can be secured by damping the paths and borders at closing time. Before nightfall admit a little air at the top of the house, damping with liquid manure. Thinning the berries must be attended to and followed up persistently. Remove all surplus bunches in good time. Stop or remove all laterals not required, letting those retained extend

where space permits. Do not crowd the foliage, and never allow the laterals to interfere with the principal leaves. Supply water or liquid manure to the borders liberally when needed, and encourage surface roots with suitable top-dressings. The night temperature should be kept at 60° to 65°, 70° to 75° by day, and 80° to 90° from sun heat.

Late Vines.—These are advanced for flowering, and many are in bloom. When out allow a night temperature of 70°, and 80° by day, advancing to 85° or 90° from sun heat, with a free circulation of air, a genial atmosphere being maintained by damping the paths and borders. Brush the shy-setting varieties over with a camel's hair brush, and fertilise the bunches carefully where there is a deficiency of pollen. Up to and after flowering the night temperature should be kept at 65°, 70° to 75° by day artificially, keeping at 80° to 85°, or 90° through the day with moderate ventilation in bright weather, and abundant air when mild.

THE BEE-KEEPER.

FOUL BROOD.

It is a serious matter to a bee-keeper when, through no fault of his own, he suddenly finds a strong colony of bees in his apiary attacked with this dread disease. A case to point has come under our notice during the past few days. Owing to causes which need not be here explained, a bee-keeper last autumn found two of his stocks queenless. Seeing an advertisement from an apiarian in a neighbouring county offering queens, guaranteed healthy and free from disease, he obtained two, the seller assuring him foul brood was unknown in that district. They were safely introduced, and all was supposed to be going on well, until, on examining them for the first time this spring, the purchaser found one of them a mass of foul brood.

We advised summary measures. The bees were suffocated the same night, and with the stores and frames were committed to the flames the following morning. The hive and floor board were placed in a large copper and boiled, and, after being painted, will be used again. Numerous other stocks were within a few yards of the affected hive, and the chances are that other colonies will become affected. What can be said of the bee-keeper who will thus send diseased bees throughout the length and breadth of the land? As the law now stands we think the purchaser would have a difficulty in obtaining compensation. There is no doubt about the disease coming in this manner, as there had never been known a case of foul brood within many miles of the apiary in which the queens were introduced.

HIVES FOR GENERAL USE.

It is a debateable question as to which is the best hive for general purposes, and also whether the frames should be long or short, deep or shallow. Bee-keepers, as a rule, favour these, and we think rightly so, with which they have had experience and obtained the greatest amount of success. But as so much depends on the management of the bees kept under various conditions, combined with the capabilities of persons in charge, that it is not safe to aver that a hive of certain dimensions is the only one to insure success. The fallacy of doing so is apparent to all who study the subject from a practical point of view. But if we can have a recognised size, both for the hive and the frame, such as may be useful in various parts of the country, and from which a good surplus may be obtained in ordinary seasons, it will in the end be of great assistance to bee-keepers. By having all frames in the apiary (whether large or small) made of the same dimensions, they are interchangeable one with the other. The convenience of this is well known to those having several stocks under their charge. One is then able to assist weak colonies with a frame of brood if required, and it is also desirable in the matter of stores. However carefully the bees may be fed in the autumn, there is always a great difference in the spring, when some stocks will be found on the verge of starvation, whereas others will have enough and to spare, and a frame of stores removed in this way from the latter and given to the former will be found to answer much better in practice than giving artificial food.

As regards the size of the hives, it is immaterial so long as there is sufficient space at disposal to expand the brood nest as required. This should not be too large, or if large may be reduced by removing several frames, when a surplus is coming in freely, so that it may be stored in supers. But as the size of hives has been discussed in recent notes it is not necessary to again give the dimensions of those most favoured by us.—AN ENGLISH BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

W. J. Godfrey, Exmouth.—*Carnations*.
R. C. Notcutt, Ipswich and Woodbridge.—*Dahlias, Begonias, and other Plants*.

TO CORRESPONDENTS

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Warts on Vine Leaves (M. B. R.).—The excrescences are as likely to occur on the Gros Colman leaves with the atmosphere too dry, as when kept in a genial state. As you see on page 386 Mr. Buchanan found that by preventing currents of air through the front sashes he preserved the foliage of Gros Colman in a healthy condition. We have observed similar results coupled with shading a Vine when the leaves were prone to depart from a normal state. The cultivator mentioned did not find shading of service in the north. The early ripening is the result of the prematurely hardened condition of the leaves.

Chamaepeuce diacantha (J. F.).—The position is not at all suitable for the seed pan; had you placed the pot in gentle heat, a frame on a mild hotbed answering well, the seed would most probably have germinated in about three weeks. If you are in a position to do so shift the pot at once to heat, continue to shade, and keep the soil uniformly moist as before, and according as the seedlings (they sometimes come up very irregularly) are large enough transplant singly to small pots, moving them with a label, so as not to greatly disturb the rest of the soil. If kept growing in gentle heat a few plants may possibly be sufficiently well rooted to plant out early in June. Once they commence growing progress is rapid. These Fish-bone Thistles can be raised from seed in the autumn, but the plants are difficult to keep during the winter.

Liquid Manure for Strawberries (New Reader).—There is no better liquid manure for Strawberries than the drainage from manure heaps or sewage, but when these are not obtainable guano water may be used, and has often been applied with great benefit. Half an ounce dissolved in a gallon of water is sufficient for plants in pots, but twice that quantity may be applied safely to established plants that need extra support in the open air. It should not be poured on the fruit or leaves, only on the soil, copiously, and if this can be mulched afterwards for the retention of the moisture it will be an advantage. It is an excellent plan to give liquid manure as soon as the fruit is set, then cover the ground with straw or other suitable material for keeping the fruit clean and preventing the evaporation of moisture from the earth. The use of liquid manure should be discontinued when the fruits commence colouring.

Silver Leaf in Peach Tree (Gardener).—The affection is common with Plums, the upper cuticle usually separating from the substance beneath, and hence giving an appearance of transparency. In some that we had microscopically examined no fungus was discovered, and no cause for the state of the leaves could be ascribed or remedy suggested. In the Peach leaves sent a fungus has been found by Mr. Abbey, of which an illustration will be given in a future issue. There is not time for its preparation this week. We do not think the affection would arise from the trees having a large quantity of wood cut out of them, but the fungus would be favoured by faulty ventilation. The casting of the fruit indicates imperfect maturity of the wood, and we should endeavour to have it well ripened this season, so as to secure a better result another year. The trees would be improved by a top-dressing of the following mixture:—Dissolved bones, dry and crumbling, five parts; double sulphate of potash and magnesia, three parts; and one part sulphate of iron, mixed, using 4 ozs. per square yard, and pointing-in very lightly. If the trees produce long-jointed sappy wood it would be advisable to lift them, partially or entirely, in the autumn, or at least root-prune, to secure a mass of fibrous roots in the surface layer of a firm yet porous border.

Sulphate of Ammonia and Sulphate of Iron as Manure for Plants (Amateur).—If you propose to use the substances in mixture the proportions should not be more than $\frac{1}{2}$ oz. sulphate of ammonia and $\frac{1}{4}$ oz. sulphate of iron per gallon of water for plants generally; for such delicately rooted plants as Rhododendrons use double the quantity of water to the $\frac{3}{4}$ oz. of mixture. The articles are useful, but only supply nitrogen, iron, and sulphur, the two former accelerating growth and deepening the colour of foliage. They must not be used too often, about once a week usually sufficing. Neither is desirable for mixing with soil, but some use about a teaspoonful to a peck, mixing well before potting. The use of the ingredients on the soil in pots should not be more in mixture than a pinch, as of snuff, between the finger and thumb for a 6-inch pot, sprinkling evenly and at once washing in.

Rootless Hippeastrums (Amateur).—The plants are probably suffering from overwatering, which has caused them to decay through sourness of soil. The bulbs should be quite dry in winter, and kept so till growth starts, then plunged and syringed, watering carefully till leaves show. If in bottom heat all the better. As the plants are only pushing flower buds now it is questionable if they can be made into healthy plants, but we should try the effect of bottom heat if any be at command, keeping the soil only moderately moist. Perhaps, however, they have the roots destroyed by mites or other pests, many bulbs having the life taken out of them by the insidious foes living between the outer scales and at the base, whence should spring the roots, but cannot through the nuclei having been destroyed. In that case nothing will be of any use until the pests are destroyed. Where they exist the simplest is to subject them to water at a temperature of 130° to 135° for about five minutes, and afterwards repot, giving bottom heat, sprinkling occasionally, but affording little water at the roots until these have well hold of the soil. A bottom heat of 80° to 85° usually causes free rooting, and helps the plants forward famously.

Paris Green (M. O.).—This compound, though poisonous and requiring great care in using, is nevertheless one of the finest remedies known for destroying the small but destructive larvæ of the winter codlin, lackey, magpie, and umber moths, which annually work havoc with the young foliage, the flowers, and often the fruit of Apples, Pears, and Plums. During the blossoming period it is unsafe to apply Paris green on account of the bees which, visiting the flowers, perform substantial service in aiding fertilisation. When, however, the flowers have decayed, and attacks of the larvæ are imminent, spraying once a fortnight for some weeks with Paris green will prove a most effectual remedy. To apply it so that it acts destructively to caterpillars or other pests it must be distributed in a fine mist-like spray, both on the under and upper surfaces of the leaves where it is deposited as a thin film or sediment. Through this the young caterpillars have to pierce to find the juicy food they seek, but in doing so they imbibe the poison which quickly kills them. The proportions of Paris green and water are 1 oz. to 20 gallons of water. This is safe for tender foliage. Paris green is obtainable both as powder and paste; the latter is the safer and better because it is more easily mixed with water. The best instruments for delivering the mixtures are either a knapsack pump, or some other spray distributor.

Young Cucumbers Turning Yellow and Decaying (G. R.).—The young Cucumbers are attacked by a spot fungus (Colletotrichum lagenarium, syn. Glæosporium Lindemuthianum), which occurs in several Continental countries and over a large portion of the United States. It has also been found in this country during recent years, both outdoors on Scarlet Runners, Ridge Cucumbers, Gourds, and Vegetable Marrows, and indoors on French Beans, Cucumbers, and Melons. It seldom does any great mischief, except during rainy or a long spell of warm, moist weather, and in structures kept too close and moist. The only preventive we have found has been the use of a little sulphur on the hot-water pipes, and maintaining a temperature of 65° to 70° at night, 70° to 75° by day up to 85° , 90° , or 100° from sun heat, not giving more moisture than is absolutely necessary for the health of the foliage. Spraying with quarter strength Bordeaux mixture has been advised, but unless begun early, say when the plants are about three weeks old, it has little effect. Cut away all the affected fruits and burn them. The fungus goes over partly on diseased seeds, and then appears in the young plants, commonly killing them, and the spores thus produced attack large plants, producing "spot" or canker on the pods of Beans or fruits of Cucumbers or Melons. Affected seeds are easily recognised by their dark shrunken spots. We have tried pickling the seed similar to Wheat with sulphate of copper, but find the Jensen process of steeping in water at 135° for about five minutes before sowing the safer practice.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (H. S.).—1 and 2, forms of *Cattleya Mendeli*; 3 and 4, poor varieties of *C. Mossiæ*; 5, *Bifrenaria Harrisonæ*. (D. W. B.).—1, *Pyrus spectabilis*; 2, *Lonicera tartarica*; 3, *Prunus*

(*Cerasus*) *padus*. (W. G.).—1, *Fuchsia procumbens*; 2, *Anthericum variegatum*; 3, *Sparmannia africana*; 4, *Hibiscus sinensis*. (T. B.).—1, a good dark variety of *Lælia purpurata*; 2, *L. elegans*. (S.).—A form of *Odontoglossum Andersonianum*.

THE OLD STORY.

WE live in an age of science, we are full of excellent modern inventions, improvements greet us on every side, and yet how helpless we are in many ways and many things. It is perhaps just as well that it is so. If everything came easily to our hand, where would be our energy and industry? Sometimes, however, we feel ready to sit down and give up. We have exercised our greatest skill, we have spared neither pains nor expense, and then, possibly when we hoped to see our labours rewarded by a grand crop, the seasons have proved disastrous, and our bright prospects have been dispersed like dew before the rising sun.

In visitations of this nature we trace the hand of Providence, and

we, like the patriarch of old, say, "Shall we not receive good at the hand of God, and shall we not receive evil?"

But there are other difficulties with which we have to contend, neither unexpected nor unusual; and though they are of yearly occurrence, from the letters we read in the papers, and from the excellent advice given, we might imagine they were quite new obstacles, of the treatment of which the writers knew nothing whatever. We refer to the earth's most fruitful crop—weeds, in their multifarious forms. "Thorns also and thistles shall it bring forth," was the verdict in the world's early days, and that sentence has never been revoked. Whatever other seeds fail to germinate, there is no fear of the failure of the weed crop.

We should like to know a few particulars of a good farmer's labour bill for weeding alone; it would startle some of us considerably. We fancy the last few years have seen much less done in the way of hoeing Wheat; of course the crop has been by no means a paying one, and the farmer has been of necessity obliged to curtail his labour as much as possible. We own to liking to see clean Wheat stubble after harvest—it looks more workmanlike.

If Wheat has been neglected, the root crops will not allow themselves to be put on one side. The tender little plants, often struggling against adverse climatic influences, must at all cost be saved from death by smothering; and in the freshly tilled ground, rich with manure, the weeds grow faster than the legitimate plants. There is one crop that acts as a grand weed-killer. Nothing can flourish where strong Potato tops abound, and the process of lifting makes the work complete.

We have always held an idea that constant and incessant cultivation were the only methods of keeping weeds at bay. The seeds come from no one knows where, and some have a marvellous power of lying dormant for years, and germinating when brought to the surface by extra deep cultivation. There is one weed in particular which is much in evidence just at this season of the year—we refer to "charlock," "ketlock," or "brassacs," these different names being local. The seed is oily in its nature, and therefore, as we said before, will exist unsuspected for years. One thing alone is fatal to the young plant, and that is frost. In Barley fields we may see it by millions, and the spring frosts are not sufficient to destroy it; the only course appears to be the harrow, but there again we are fast, for if the Clover seeds happen to have been sown—no harrow must go near. Of course there is the old process of hand-pulling—very laborious, very dear, but most effective; in fact, we feel that after all old-fashioned farmers knew a thing or two, and employed means that, though costly at the outset, proved the cheapest in the long run.

There is nothing but the hoe for Turnips and Swedes, for the rich superphosphates encourage and foster the ketlock as much as the little Turnip plant. Root growing has always been, and must ever continue, a costly process; but we can find no substitute for them.

We are always ready to greet with pleasure any labour-saving appliance; but we, being of a cautious temperament, prefer that our neighbour should take the risk of first experiment. We have read with interest an account of a new weed destroyer that will, if it comes up to the expectation of the discoverer, revolutionise the science of weed destroying. As is the case usually, the discovery was accidental. The owner of a French vineyard, in spraying his Vines, noticed that the mixture used completely destroyed plants of charlock.

Following up this success, an experiment was made on a field of charlock and Oats, with the result that the weed succumbed, while the Oat crop remained uninjured. Last June the experiment was again tried on a piece of Oats, a good crop so far as charlock and wild radish would allow. The spraying mixture used was a solution containing 5 per cent. of sulphate of copper. The weeds turned from yellow to black, and the Oats, which on first appearance looked sickly, quickly recovered tone. Among the Oats were plants of Red Clover, which assumed much finer proportions than that Clover which had been outside the treated portion of the field,

Had the sulphate of copper wrought the improvement, or was it simply because, the noxious weed being gone, the valuable plant had more room for food and development?

In another case a Barley crop was chosen for the experiment, and as sulphate of copper is a costly material, sulphate of iron was used instead, a solution containing 30 per cent. of iron. The mixture was sprayed in the evening of August 20th; a heavy rain fell some hours later, and in the morning the charlock plants were found to be dead or dying. The Barley received a check which arrested its growth for a few days.

In another set of experiments it was satisfactorily proved that 10 per cent. of sulphate was sufficiently strong to kill all weeds. If, as stated, the cost per acre is about 3s. 2d., this new discovery is a very valuable one. There would be, too, the initial cost of the spraying machine; but this, we should think, need not be a serious consideration. Such a machine could be hired out throughout the length and breadth of a parish.

It would be much more portable than a threshing machine, and it would pay for itself many times over.

WORK ON THE HOME FARM.

At last we have three fine days in succession and are able to set drags and harrows to work once more with a fair prospect of benefiting by the work done. We are dragging fallows through, and harrowing after a day's interval has allowed the surface to dry; another harrowing will follow, then the roll and harrow again, when the little bits of twitch still left should be on the surface clear of soil, and in a fair way to die if the weather will keep dry enough to allow them to do so.

Ridge harrows are kept constantly at work amongst the Potatoes, some of which will soon be putting in an appearance above ground. As there is still a little danger of frost we are ridging these up afresh to keep them out of harm's way a little longer. Apart from that consideration the ridging and subsequent horse-hoeing down again must save manual labour.

We begin to see many thistles amongst the corn, and "All hands to the hoe" will be the cry. Wheat at present, or rather at prospective autumn prices, should be worth a little more labour than it has been given of late years, and as far as possible we shall give ours a thorough hoeing. This will occupy the men this month out. The spring corn must be weeded, and this work can be very well performed by women if they can be had and the weather be decently fine. Women are very quick at detecting weeds, but do not like working amongst wet corn, particularly amongst Wheat, which, being so much higher and stronger than Barley, often is hardly ever dry, even in fine weather, if the dews are heavy; so to make the best of female labour keep it amongst the Barley. We can get strong girls at 1s. 3d. per day, and two will do more than one man.

The hoe, like every other tool, should be kept in good order and fairly sharp at the edge; it should be capable of doing its work without rough usage, and should never be handled as if the workman were chopping wood. If the hoe be lifted high from the ground it often misses its intended mark and cuts up corn instead of weeds, whilst the latter requires another stroke, and time and strength are both wasted.

REMARKS.

8th.—Overcast, with drizzle and slight showers early, and in afternoon.
9th.—Overcast, with occasional gleams of sun in morning; bright sun from 3 P.M.
10th.—Rainy early and at night; overcast throughout, with spots of rain at times.
11th.—Gale and heavy rain in small hours; windy and brilliant day, but spots of rain at noon, and a shower at 7 P.M.
12th.—Generally overcast with spots of rain in morning, and a heavy shower at 5 P.M., but occasional sunshine.
13th.—Brilliant till 9 A.M., frequently cloudy after; spots of rain at 4.30 P.M.; heavy shower at 7 P.M.
14th.—Heavy showers early; alternate cloud and sunshine during day.
Rain every day, but the aggregate depth not half an inch.—G. J. SYMONS.

W. CLIBRAN & SON'S

DESCRIPTIVE CATALOGUE

OF

Garden & Conservatory Plants.

Replete with invaluable information, is sent post free to any address on application. Buyers are invited to inspect the magnificent representative collections of every class of these plants at the **OLDFIELD NURSERIES, ALTRINCHAM**. To those who cannot come the fullest information as to price, sizes, &c., will be sent on request.

HERBACEOUS, ALPINE, AQUATIC, AND BOG PLANTS.

Of these alone the stock numbers several hundred thousand plants, all of the very best procurable types.

COLLECTIONS (our Selection only):—12 sorts for hot dry situations on Rockery, Walls, &c., 4/-; 12 for moist shady Rockeries, 4/-; 12 for sunny borders, 4/- and 6/-; 6 Aquatic plants for deep water, 6/-; 12 Aquatics for boggy places, 4/- and 6/-; Asters (Michaelmas Daisies), 6 sorts for 2/6, 12 for 4/-, 25 for 7/6; Sempervivums, 12 sorts from 3/6; 50 fine showy Border perennials in 50 varieties, 15/- and 21/-; 100 ditto, in 100 varieties, 35/- and 42/-. As all these plants are supplied in pots, they may be planted out practically at any time.

HARDY CLIMBERS FOR OUTDOORS.

(Our Selection.) Clematis, 12 fine sorts from 10/6; Ivies (finest green and variegated varieties), Honeysuckles, Wistarias, self-clinging and other Virginian Creepers, Ceanothus, Menispermum, Aristolochia, 12 fine sorts in pots, 12/-.

CLIMBERS FOR GREENHOUSE AND CONSERVATORY,

Including Passion Flowers in great variety. Stephanotis (the freest blooming form), Clorodendron Balfouri, Lapageria (finest varieties), and many others at 10/- and 30/- per dozen and upwards, according to size.

STOVE AND GREENHOUSE PLANTS, FERNS, &c.

12 varieties flowering Stove Plants from 10/-; 12 varieties foliage Stove Plants from 18/-; 12 varieties Greenhouse Plants from 12/6; 12 varieties Caladiums from 12/-; 12 varieties Crotons from 24/-; 6 Epiphyllums from 7/6; 12 distinct named Gloxinias from 18/-; 12 Streptocarpus seedlings, in 3 inch pots, from 6/-; 12 double seedling Begonias, finest selected, true to colour and shade, 12/- to 30/-; 12 distinct Ferns for stove from 9/-; 12 ditto for Greenhouse from 6/-; 12 different Adiantums from 6/-; seedling Ferns for Rockeries, Table Decoration, &c., from 3/- per dozen.

DOUBLE CACTUS DAHLIAS.

SPECIAL OFFER.—12 splendid Cactus Dahlias, including the following superb Novelties of 1897:—Cycle, Ensign, Flossie, Harry Stredwick, and Mrs. Kingsley Foster, together with Beatrice, George Marlow, J. E. Frewer, Lady Penzance, Mrs. Wilson Noble, Mrs. Francis Fell, and Viscount Boyne. Post free, 12/6.

Clibrans, Altrincham & Manchester

TO GARDENERS (Amateur and Professional).
Competitors at Horticultural Shows, and Others.

NITRATE OF SODA

THE NITROGENOUS FERTILIZER. — Indispensable for **VEGETABLES, FRUIT, AND FLOWERS.**
MAY BE BOUGHT OF ALL SEEDSMEN.

Price, in tins containing 4 lbs., warranted of standard purity, with full directions for use, ONE SHILLING; also in SIXPENNY Tins, containing 1½ lbs.

Books and Pamphlets on the use of NITRATE OF SODA on the Farm and Garden, free and post paid, on application to the

PERMANENT NITRATE COMMITTEE,
3, GRACECHURCH STREET, LONDON, E.C.

CARTERS' TESTED SEEDS.—
In Sealed Packets. Post free. Price 2/6, 3/6, and 5/- each.

CALCEOLARIA, CARTERS' VICTORIA.—
The finest in the world. Real gems of splendid habit.

CINERARIA, BRILLIANT PRIZE.—
Brilliant colours, endless variety. The grandest strain ever seen.

PRIMULA, HOLBORN PRIZE.—
Grand blossoms of rich colours. Single varieties, choice mixed colours; double varieties, choice mixed colours. Single, in separate colours, viz., blue, scarlet, rose, or white. Double, in separate colours, viz., crimson, lilac, rose, or white.

GLOXINIA, CARTERS' INVINCIBLE.—
Magnificent blooms, brilliant colours. These cannot be surpassed.

The above in Sealed Packets, post free; price 2/6, 3/6, and 5/- each.

CARTERS', THE QUEEN'S SEEDSMEN,
237, 238, and 97, HIGH HOLBORN, LONDON.

TREE TOMATO.—Grand New Hybrid, no stakes required. Dwarf and easy to grow, heavy cropper, fine fruit. Good for open-air culture. (See illustration, *Amateur Gardening*, April 16th.) Plants, 3 for 2/-, 6 for 3/-, or 5/- per dozen, free for cash.—R. HOLMES, Norwich.

100,000 VEITCH'S AUTUMN GIANT CAULIFLOWER PLANTS, 3/6 per 1000; Dalkeith Brussels Sprout, 2/6; Drumhead Cattle Cabbage, 2/-; Grand New Strawberry Monarch, 7/- per 100; in 60's pots, 12/- 100. 3-year Connover's Colossal Asparagus, 4/- per 100.—W. HORNE, Cliffe, Rochester.

DEFY THE BIRDS by Buying our Noted **ROTLESS TANNED NETTING**, as supplied to the Principal Gardeners in the Kingdom. Orders over 5/- value are sent Carriage Paid. 100 yds. by 1 yd., 3/-; 200 yds. by 1 yd., 6/-; 300 yds. by 1 yd., 9/-. Can supply any length and width.—**UNIVERSAL SUPPLY ASSOCIATION**, East Street Works, Reading. (Name Paper.)

HEATING APPARATUS.—Medals 1875 and 1881. Catalogue of Boilers, Pipes, and Fittings free. W. Jones' Treatise, "Heating by Hot Water," second edition, 216 pages, 2/6; post free, 2/10.—**JONES and ATTWOOD**, Stourbridge.

FORMICACIDE ANT DESTROYER thoroughly destroys all ants and insects in greenhouses and other places troubled with ants. Sold in bottles, 1/-, 1/6, 2/6, and 4/-.—**CORRY & CO., Ltd.**, 16, Finsbury Street, London, E.C., and from all Seedsmen and Florists.

Bougainvillea Cypherii.

GRAND NEW PLANT.

Largest and best coloured Bougainvillea ever offered. A splendid grower and remarkably free bloomer. Awarded First-class Certificate at the Wolverhampton Floral Fete, 1896, and the Oxford Commemorative Show, 1896, and the Gold Medal at Shrewsbury Great Royal Commemorative Show, 1897, for the best new plant in the exhibition. **JAMES CYPHER** has great pleasure in offering this grand novelty. Plants ready end of May, price 10/6 each.

EXOTIC NURSERIES, CHELTENHAM.

FUCHSIAS, GERANIUMS, DAHLIAS.

12 fine varieties of **FUCHSIAS**.
12 **GERANIUMS**, Double, Single, or Ivy-leaf.
12 **DAHLIAS**, Show, Fancy, or Cactus.
All in new and finest varieties; nice strong rooted plants, my selection, post free for 7/6. Every attention given to purchaser's wishes.
Amateurs should see **CATALOGUE**, which contains ample Directions How to Grow, Show, and take Prizes.
R. PANNETT, Florist, CHAILEY, SUSSEX

HOOPER'S PANSIES

THE FINEST STRAIN IN THE WORLD.

Has been Awarded upwards of 50 Medals by R.H.S. and R.B.S. of London.

12 Grand Exhibition Varieties, 3/-; 12 Champion, 4/-; Seed saved from 2000 Exhibition Varieties, 1/-, 2/6. Packet, free for cash.]

HOOPER, Pansy Grower, BATH.

THE "SPROUGHTON" HOE.

Simpler than the Dutch Hoe and much superior. The most perfect Duplex (Push and Draw) Hoe yet made. Highly approved at Chiswick (R.H.S.), and at the Royal Gardens, Windsor. Strongly commended by Sutton & Sons, Mr. E. Molyneux, and other leading horticulturists. Copies of testimonials from Rev. A. FOSTER-MELLIAR, Sproughton, Ipswich. Price 1/10 each. Of all Ironmongers, or of

Messrs. RANSOMES, SIMS & JEFFRIES,
PRINCES STREET, IPSWICH.

Journal of Horticulture.

THURSDAY, MAY 26, 1898.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St. London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

THE TEMPLE SHOW.

FOR the eleventh time the Summer Show of the Royal Horticultural Society will, on the day of publication of these lines, be displayed in the fine open space known as the Temple Gardens. It is an ideal place for a large show, kindly placed at the disposal of the Society by the Benchers of the Inner Temple, and the favour cannot be too highly appreciated.

Naturally the authorities cherish the fine open lawn, and it speaks well for the show managers that the sward is not injured, though an enormous extent of boarding is necessary for its preservation. The only effect of the covering is to turn the grass a paler green, but it assumes its ordinary hue in the course of a very few days after the flooring is removed.

Not the least advantage of the site is its accessibility. The northern entrance to the Gardens can be reached in two or three minutes by various outlets from Fleet Street; while on the much longer south side runs the splendid promenade, the Thames Embankment, from which the greater number of visitors enter the enclosure.

The shows have increased in magnitude till the full amount of disposable space is occupied. If convenience could be afforded for all the plants, flowers, and other produce that cultivators would like to arrange, the exhibitions would, large as they are, doubtless be as large again; but it does not follow that they would be as good again, as there would be much more duplicating, while, as a rule, the closer the selection the higher the quality and greater the merit of the respective groups.

Moreover, the display is large enough to satisfy all reasonable visitors, and if absence of complaints on the question of extent is a criterion, the show does satisfy them, for we have heard of no such complaints; while as to quality, diversity, beauty, and interest of the exhibits individually, they are, on the whole, and in their several and varied features, unsurpassable. Collectively the best is done that can be done to produce an imposing effect.

The Temple Shows differ from all others.

There is no schedule of specified classes, but varying amounts of space are allocated to applicants, and they occupy it with the best products at disposal. This permits, not only of large and splendidly grown plants being arranged, but also of smaller, which are rich and rare, or the latest and best introductions, or home-raised varieties, being placed before the public.

Then, in addition to the plants, and an important addition too—fruits and vegetables, both in the guise of bearing trees and plants, as well as in dishes of the best kinds and quality which the season affords, go to form in its entirety the best and most complete representation of British horticulture that can be seen at the end of the "merrie month of May."

From end to end of the show there can scarcely be less than half a mile in length of groups of plants, flowers, and other products of the nature indicated, arranged on the tables, in banks, or other forms for inspection, besides outside exhibits, and we are at liberty to believe that, taking the several components of the exhibition all in all, they could not, in intrinsic merit, be equalled by any country in the world, though some other nations have the means for making more striking spectacular displays.

Unfortunately to-day the great Derby is run at Epsom, and this may have a prejudicial effect upon the number of visitors. This, however, can only be decided when the day is past. It is practically certain that the Temple Show will not be honoured by the presence of any members of the Royal Family, as has been the case in years past, and this loss can only be attributed to the above cause. We are glad to say that the show was opened in fine though dull weather.

Enter now the reporters. They have only a few hours in which to do the best they can, and as they have nimble pens or pencils, and printers' imps to rush to and fro, snatching the sheets from their fingers, we trust to their giving not a discreditable account of the great show, which opened yesterday, and of themselves as narrators, as they march along the avenues of beauty.

ORCHIDS.

Numerically the Orchid department of the exhibition shows a slight decline, as two or three exhibitors who last season staged excellent groups have this year fallen out. Baron Schröder's superb Orchids are missed, as are the *Odontoglossums* of Mr. Ellis. However, the difference in numbers is by no means sufficient to mar the success of the display as a whole; indeed, the spectacle is a singularly brilliant one. The central table of the large marquee, except a small space occupied by new plants, is full of Orchids from several well-known growers, while a portion of the second tent is similarly occupied. As is customary the vast majority of the plants are of comparatively well-known kinds, but some new ones are also to be seen, and several of them are of the first merit. *Cattleyas*, *Lælias*, *Odontoglossums*, and *Cypripediums* are all magnificently represented in the various stands, of which particulars are given below.

As has been the case at several Temple shows, Messrs. Sander & Co., St. Albans, occupy the most conspicuous position immediately within the large tent. Their display is always an imposing one, as the firm stages splendidly grown plants, carrying flowers of good size, substance, and beautifully coloured. It would be obviously impossible to mention every individual plant in either this or the other groups in the limited time at disposal, and it would serve no practical purpose. We shall, therefore, content ourselves with a selection of the most conspicuous, which included *Cypripedium callosum* Sanderæ, *C. bellatulum* album; *Cattleyas* Wagneri, Mendeli, Mossiæ, William Murray; *Oncidium ampliatum* majus, *Masdevallias*, *Odontoglossum crispum*, *Epidendrum Randi*, and others.

The group from Messrs. H. Low & Co., Bush Hill Park Nurseries, Eufield, is a very charming one, and the best use has been made of the space, and the well-grown plants, so far as effect is concerned. It is beyond question a very fine exhibit, and one which does credit to its producers. Amongst the many splendid plants comprised, a few of the choicest are *Cattleyas* Mossiæ, *M. Reineckiana*, Mendeli, Wagneri; *Lælia purpurata* Russelliana; *Odontoglossum crispum* in charming variety; *Cypripediums* Gertrude Hollington and Mastersianum; *Odontoglossum* Pescatorei, *Lælia elegans* Lowiæ, *Oncidium sphacelatum*, *Odontoglossum Dieu Donné*, a superbly coloured Mendeli, and *Dendrobium Dalhousianum* Salmonæ, a lovely variety that is unique.

The next stand to claim attention is smaller than either of the foregoing, but is none the less worthy of attention, for it is the result of an amateur's efforts. It is from Mr. Hislop, gardener to H. S. Leon, Esq., Bletchley, and is highly creditable. The several Orchids are examples of good culture, and we may enumerate as amongst the most praiseworthy

Cattleyas Skinneri, Mossiæ, and Mendeli; *Lælia purpurata*, *Dendrobiums*, *Vanda teres*, *Odontoglossums* crispum, and Pescatorei, *Cattleya Schroderæ* alba, *C. speciosissima* Ernesti, and *Cypripediums*.

Messrs. Charlesworth & Co., Heaton, Bradford, cannot be regarded as regular London exhibitors, though we occasionally see them at the fortnightly Drill Hall meetings, and they invariably stage effectively. Such is the case on this occasion, their examples of *Cypripediums* Schofieldianum, Rothschildianum, caudatum; *Cattleyas* Skinneri, Mossiæ, Mendeli, F. Denis, and Lord Masham; *Odontoglossums* crispum Princess, and cordatum; *Lælio-Cattleyas* Cinna-brosa, and radiata, *Oncidium*, *Masdevallias*, *Miltonia vexillaria*, *Vanda teres* being very fine.

Very beautiful is the assortment sent by Mr. W. Stevens, gardener to W. Thompson, Esq., the celebrated Midland amateur, from Walton Grange, Stone, Staffs. It is evident that all the gems of the collection were not disposed of at the recent sale, for we observed such excellent Orchids as *Odontoglossum crispum* Lily, Capartianum, Prince Charming, Dorothy, Thompsonianum, and fastuosum, Wilckeanum grandis, Andersonianum, excellens, and tripudians.

It is pleasant to observe that a London amateur is contributing to this unique exhibition of Orchids, for it proves that the plants are, to a certain extent, amenable to culture in towns. The group referred to is from Mr. J. Clarke, gardener to Ludwig Mond, Esq., The Poplars, Avenue Road, Regent's Park, who staged *Cattleya Mossiæ* Mondi, *Oncidium ampliatum* majus, *Odontoglossum* Andersonianum, *O. citrosimum*, *O. crispum*, and *Cymbidium Lowianum*.

The north of London is handsomely represented by two firms, the first to take our attention being Messrs. B. S. Williams & Son, Upper Holloway, who show in the charming style that has become characteristic of the firm. Though this particular group is really one of Orchids, the effect has been enhanced by the judicious admixture of graceful Ferns and Palms. Of the Orchids that here find a place the best are forms of *Odontoglossum crispum*, *Oncidium*, *Calanthes*, *Lælia purpurata*, *Cypripediums*, *Miltonia vexillaria*, *Lælia Latona*, *Vandas*, and several others.

So far as size is concerned the first amateur exhibitor is undoubtedly Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, whose arrangement is very imposing. It occupies a position at the end of the central tent, and attracts attention by the diversity and beauty of its many parts. As is customary, Mr. White has utilised numerous Orchids of botanical interest, several of which possess structural peculiarities that always take the attention of visitors. There are, of course, others of far showier character, and which do much to brighten the group. Perhaps the most conspicuous are *Miltonia vexillaria* in variety; *Cattleyas* Mendeli, Skinneri alba, Mossiæ, and M. Wagneri; *Lælia purpurata*; *Cypripediums* Lawrenceanum, *Hoo eræ* voluteanum, Curtisi, barbatum, Dautheiri, Eleanor, Olenus Burford var., and superbiens; *Odontoglossum crispum* in variety; several *Dendrobiums*; *Brassia verrucosa*; *Cymbidium Lowianum*, *C. tigrinum*; *Masdevallias*; the blue *Dendrobium* (*D. Victoria Regina*); *Aganisia cœrulea*, *Habenaria rhodochila*, and *Microstylis macrophila*.

A cleverly arranged group is one from Mr. W. H. Young, Orchid grower to Sir Frederic Wigan, Bart., Clare Lawn, East Sheen, who utilises his excellently grown plants to the best advantage. The "greenery" employed sets off the bright flowers of the Orchids in a very pleasing manner. *Cymbidium Lowianum*, *Lælia purpurata*, *Miltonia vexillaria*, *Cypripedium caudatum*, barbatum, Lawrenceanum, *Cattleya Mossiæ*, *C. Mendeli*, *Odontoglossum crispum*, *Cypripedium callosum* Sanderæ, several *Oncidium*s, and others were very charming.

The Orchids employed by Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, are of a more homely character than are hundreds of others in the show. This is explained by the fact that they are cultivated for home adornment. Interspersed amongst them are foliage plants, and the group, though perhaps slightly crowded, is nevertheless a very creditable one. We observed amongst others *Cypripedium* Lawrenceanum, *Odontoglossum crispum*, *Cymbidium Lowianum*, *Cattleyas* Mossiæ and Mendeli, *Lælia purpurata*, with *Dendrobiums*, *Oncidium*s, and others in variety.

Mr. W. S. Buckill, gardener to Malcolm S. Cooke, Esq., Kingston Hill, S.W., shows a small group of Orchids in capital condition, which adds its share to the general display. This exhibitor stages some charming spikes of *Odontoglossum crispum* and Pescatorei, *Miltonia vexillaria*, a number of *Cymbidium*s, *Cattleyas*, *Masdevallias*, *Brassias*, *Cymbidium*s, and *Dendrobiums*.

The last exhibitor of Orchids to be noted as staging in the big tent is Mr. J. Cypher, the celebrated Cheltenham grower. He is the only representative from the West of England in the show, and his assortment is exceptionally fine. The grand plants carry healthy green leafage and splendidly developed flowers, that are of great substance and rich in colour. This latter feature is particularly observable in such specimens as *Lælia purpurata*; *Cattleyas* Mendeli, Mossiæ, and citrina; *Miltonia vexillaria*; *Odontoglossums* crispum, Halli, triumphans, cirrhosum, and luteo-purpureum; *Dendrobiums* in variety, *Oncidium Marshallianum*, *Anguloa Clowesi*, many *Cypripediums*, and others.

The great Belgian firm of Linden comes to the assistance of the Royal Horticultural Society with an exhibit of considerable extent. We are glad to observe that the system of staging that was adopted last year has been changed, and a much better effect is the result. The whole of the plants are species, hybrids, or varieties of *Odontoglossum*, with a number of plants of *Cypripedium* Lawrenceanum. The long graceful spikes of the former produce a very charming effect, and several of the forms, of which names cannot possibly be given, are of great merit.

In an earlier paragraph we named one of the two North London exhibits, and we turn now to the other from Messrs. W. L. Lewis & Co., Southgate, who are showing in their best style. The group is very showy, comprising as it does splendid flowers on healthy plants of *Oncidium*, *Lælia purpurata*, *Cattleya Skinneri*, *Cymbidium Lowianum*, *Cattleya Mossiæ*, *C. Mendeli*, *C. M. Amelia*, *Dendrobiums*; *Cypripediums* *Gertrude Hollington*, *grande atratum*, *Dayanum*, *Evenor*, with *Odontoglossums* and others. Smaller exhibits of Orchids came from one or two Continental and several home growers.

ROSES.

One of the features of the annual exhibition in the Temple Gardens for the past few years has been Roses, and this season's display appears to be quite equal, if not superior, to any of its predecessors. The queen of flowers attracts the attention of the visitor at different points, and each exhibit presents its own interesting and pleasing features. *Crimson Rambler* is again to the fore, displaying its sprays of brightness in almost every exhibit. A Temple without *Crimson Rambler* now would seem wanting, and though the variety is well known, it is none the less admired. Exhibitors at the great show have on former occasions shown what a Rose tree in a pot is capable of producing, and the reputation made is fully maintained. There are Roses in all forms in pots, besides fine stands of cut blooms, and it is only fair to the exhibitors, who are enumerated below, to say that they are individually and collectively a credit to the respective growers.

Mr. Charles Turner, Slough, occupies the same position as last year, and fills the end of the large tent with Roses and Carnations. Two points are conspicuously apparent in the exhibit—i.e., good taste in arrangement and superb quality in the plants and flowers. *Crimson Rambler* is represented in various forms, and it is in all respects in keeping with the surroundings. In addition to these there are superbly flowered specimens of *Céline Forestier*, *La France*, *Souvenir de S. A. Prince*, *Camille Bernardin*, *Francisca Kruger*, *Madame Lacharme*, *William Allan Richardson*, *Juno*, *Catherine Mermet*, *Marie Baumann*, *Madame Caroline Kuster*, *Madame Victor Verdier*, *The Bride*, and *Madame Abel Chatenay*. The surface of the group is undulating and pleasing, and Mr. Turner has made the best of his space without any undue crowding.

Roses are well shown by Messrs. Paul & Son, Cheshunt, who have made the best use of the space at their command by a pleasing arrangement of pot plants. Conspicuous in the exhibit is Messrs. Paul's new introduction, a rose coloured *Crimson Rambler* bearing the name of *Psyche* (see fig. 83, page 443). Elegance is one of the characteristics of this fine exhibit, and the plants are dispersed to show their beauty to advantage. It would be difficult to overrate the merits of superb standard specimens carrying large flowers, and among the numerous varieties shown in different forms are *Charles Lawson*, *Ulrich Brunner*, *Juno*, *Crimson Rambler*, and others. Altogether, the group is of an exceedingly high order of merit.

Messrs. F. Cant & Co., Colchester, show a collection of Roses in pots, mostly small plants. Teas are well represented in *Souvenir de S. A. Prince*, *Souvenir d'un Ami*, *Madame Falcot*, *Anna Olivier*, and others. *Thalia* is a pretty white *Polyantha* Rose, and is given a prominent position. The exhibit is principally one comprised of dwarf plants, and if further evidence is wanted of the usefulness of the Rose as a small decorative plant it is given in Messrs. Cant's group.

A very tasteful exhibit is that hailing from the nursery of Mr. W. Rumsey, Waltham Cross. Among the varieties represented are *Crimson Rambler*, *The Queen*, *Magna Charta*, *Ferdinand de Lesseps*, *Madame Hoste*, *Etoile de Lyon*, *Souvenir d'un Ami*, *Madame Scipion Cochet*, *Niphotos*, and *Comte de Mortemart*. In addition to the plants in pots there are numerous stands of cut blooms along the front containing many of the best known varieties.

Canterbury has become famed for Roses through the skill of that well-known grower, Mr. G. Mount, and this year his effort to maintain his high reputation is in every respect creditable. Beautifully flowered plants of *Crimson Rambler* are placed along the back of the exhibits, interspersed with *Acers*, the light foliage of which is a pleasing contrast to the crimson flowers. Principal among the cut blooms are fresh charming specimens of *Anna Olivier*, *Madame Marie Hoste*, *Niphotos*, *Mrs. John Laing*, *Catherine Mermet*, *La France*, *Baroness Rothschild*, *Ulrich Brunner*, *Général Jacqueminot*, *Madame Gabriel Luizet*, *Duke of Edinburgh*, *Perle des Jardins*, and *Fisher Holmes*.

Near to the entrance of the large tent is a fine display of Roses, for which Messrs. William Paul & Son, Waltham Cross, are responsible. There is no lack of variety in form and colour, and in pots and stands Roses of superior quality are exhibited. *Crimson Rambler* is dotted here and there, and proves a pleasing contrast to the profusion of lighter coloured varieties. Very beautiful are the flowers of *Sylph*, *Clio*, *Mrs. John Laing*, *Crimson Queen*, *Caroline Testout*, *Medea*, *Ulrich Brunner*, *Spenser*, and *Duke of York*. A feature in the exhibit is Messrs. W. Paul's new Hybrid Tea Rose, a strong scented, large flower of a rich pink. Taken as a whole, the plants and flowers are of excellent quality, and quite up to the average of the firm's former efforts.

A unique Rose exhibit is that of Mr. John Russell, Richmond, Surrey, which is composed entirely of plants of the single red Rose *Carminé Pillar*. Very pleasing are the light elegant flowers peeping from a mass of bright green, and in its own particular section the variety is one not wanting in merit.

PLANTS AND FLOWERS.

Beautifully tinted foliage and bright flowers, the like of which are rarely seen, now fill the marquees in the Temple Gardens. Some are new, as, for instance, the group of *Acalypha Sanderi*, shown by Messrs. F. Sander & Co., St. Albans, the bright rosy spikes of which attracted general admiration. Others are old, but none the less attractive. At one point there are delicately tinted *Caladiums*, at another *Crotons*, and at a third the visitor may see what experts can do with *Begonias*. There are exhibits of Ferns comprising endless variety, gaudy masses of *Calceolarias*, *Carnations* of gigantic dimensions, groups of decorative flower and foliage plants, beautiful *Clematises*, and Orchid-like *Cannas*. There are colour and variety sufficient to please all tastes, and the lover of hardy plants and flowers finds much to attract his attention. Long ranges of tabling are occupied by the members of this section, some bright and attractive, and others diminutive and inconspicuous yet possessing charms entirely their own. How to make the most of the space at command has been considered by the exhibitors, with a result that this important section of the show is as good in arrangement as circumstances will allow.

Rhododendrons in quantity are well shown by Mr. J. Waterer, Bagshot. Diversity in colour is a pleasing feature, and the varieties are dispersed with taste. Among the sorts shown are *album grandiflorum*,

FIG. 82.—*SPATHOGLOTTIS AUREO-VELLARDI*. (See page 445.)

Kate Waterer, *B. W. Elliott*, *Pink Pearl*, *Crown Prince*, *John Walter*, *Sappho*, *Countess of Normanton*, *J. Marshall Brooks*, *Princess Mary of Cambridge*, *Helen Waterer*, *Mrs. W. Agnew*, and *Duchess of Bedford*. Many of the trusses are remarkably fine, and show the full beauty of the *Rhododendrons*, both in standard form and as dwarf plants.

Messrs. J. Laing & Sons, Forest Hill, have a fine display of well grown *Caladiums*. In spite of a little flatness in arrangement the elegantly tinted foliage shows itself to advantage, and very pleasing are the colours of *Rose Laing*, *Flambeaux*, *John Laing*, *candidum*, *Marquis of Camden*, *Baron Adolphe de Rothschild*, *William Marshall*, *Charmagne*, *Sir Wm. Broadbent*, and *Gaston Chandon*. *Caladiums* with giant leaves are placed as a background, and gradually the size decreases till the front row, which is composed of varieties with diminutive foliage.

A very interesting group of plants from the nurseries of Messrs. Jas. Veitch & Sons, Chelsea, occupies a position in the large tent. The tall spikes of *Eremurus himalaicus* are dotted about in the exhibit, and rise from a groundwork of *Hydrangea japonica rosea*, *Rhododendrons*, *Azalea mollis*, *Azalea pontica Fama*, and *Gloria Mundi*, together with numerous other charming flower and foliage plants. The arrangement is light and elegant, and the group is one of the most interesting in the show, containing a happy arrangement of colour in conjunction with the excellent quality always seen in the firm's exhibits. To say that the Chelsea firm are showing *Caladiums* means that the exhibit is one of high order. Some of the specimens are of remarkable size, and in each one there is a stamp of superior quality. In the centre is a grand example of *Madame John Bosc* and others of superior character are *Sir Henry Irving*, *Mrs. Harry Veitch*, *Gaspard Crayer*, *Lord Derby*, *Williamsi*, *Clio*, *candidum*, *Silver Cloud*, *Lady Stafford Northcote*, *Henry Lovatt*, *Princess of Teck*, and *Duchess of Fife*.

Messrs. J. Peed & Sons, Roupell Park Nurseries, Norwood, are represented by a fine collection of *Caladiums*. The delicate colouration of the foliage and the healthy character of the plants are highly creditable to the firm. There is variety enough to suit the most critical taste, and among the most conspicuous are *Sir William Broadbent*, *Mrs. Harry Veitch*, *Princess Royal*, *Lady Mosley*, *Lillie Burke*, *Ibis rouge*, *Lord Rosebery*, *Princess of Teck*, *Duchess of Teck*, *Golden Queen*, *Marie*

Freeman, Louis Van Houtte, and John Laing. Tall Palms form a background, and Maidenhair Ferns are interspersed among the mass of multi-coloured foliage.

A small but excellent group of Carnations is staged by Mr. J. Jennings, gardener to Leopold de Rothschild, Esq., Ascott, Leighton Buzzard. The exhibit consists entirely of pink Malmaisons, and the remarkably fine flowers and healthy foliage are evidence that the plants have been subject to proper culture and suitable conditions.

One corner of the large tent is beautified by a superb collection of miscellaneous plants set up by Messrs. W. Cutbush & Sons, Highgate. One feature is the magnificent Malmaison Carnation, and another is the taste shown in the general arrangement. The white flowers of *Lilium Harrisii* are dotted about and make a pleasing undulating outline. Of *Azalea mollis* there are well flowered specimens, and among other plants which make up an effective group are yellow Callas, Ericas, and Crimson Rambler Roses, and along the front an exquisite finish is made with graceful *Isolepis* and Maidenhair Ferns. The arrangement of the group differs from that of any other in the show, and reflects credit on the firm.

Messrs. G. Jackman & Son of Woking have a fine collection of their hardy Hybrid coccinea Clematis. They are all charming, some climbing over wooden arches, and others trained in balloon form. Among the many varieties are Duchess of Albany, Countess of Onslow, Duchess of York, Grace Darling, Sir Trevor Lawrence, and Admiration. Seasonable hardy flowers are also shown in another tent by this firm.

Mr. W. Iceton, Putney, by his exhibit fully maintains his reputation as a grower of decorative plants. The background is an arrangement of Palms and other decorative specimens, and along the front are elegant little Caladiums, Kalosanthes, Oranges bearing fruit, Crotons, Ericas, and Ferns.

The principal feature of Messrs. F. Sander & Co.'s unique exhibit is their new introduction, *Acalypha Sanderi*, which is shown to advantage, and displays its merits as a decorative plant. Another feature in the exhibit is *Caladium lami Schwartzii*, a beautiful form of distinct habit. *Dracenas Godseffiana*, *Van der Bilde*, and *Sanderiana* are also conspicuous; and another striking plant is *Acalypha macrophylla maxima*. In addition to the above there are novelties in the form of Anthuriums, and every plant in the group possesses some interest.

Though Roses are the chief feature of Mr. Chas. Turner's exhibit, Carnations and Pelargoniums are well worthy of mention. Amongst the latter are large well-flowered specimens of Prince Leopold, Princess Teck, Spotted Beauty, Alice, Joe, and Mystery. Carnations are bearing large blooms of such varieties as Sir E. Wood, Delight, Companion, Ernest, Queen of Fancies, Sir Guy, Knight Errant, May Queen, and Delight. An interesting group of Maples hails from Messrs. T. Cripps and Sons, Tunbridge Wells. The plants are mostly dwarf, and well furnished with elegant foliage of varied hue, tints, and form.

Tuberous Begonias of the best quality are always shown at the Temple Show, and this year Mr. H. J. Jones, Lewisham, exhibits the cream of his well-known collection. From one end to the other there are none but superb flowers, both single and double. Among the most telling of the former are May Queen, an elegant flower; Mrs. Beckett, Star, Dr. Shaw, and Dorothy Linford. The flowers are borne on stout footstalks, and the foliage and general character of the plants show signs of excellent cultivation.

A fine display of colour is noticeable in the exhibit of Calceolarias, for which Messrs. J. James & Son, Farnham Royal, are responsible. The plants are dwarf, compact, and pictures of good health, while the flowers individually are large, and in a mass of colour there is ample evidence that the strain is a superior one.

Tuberous Begonias from the nurseries of Mr. J. R. Box, Croydon, make a brilliant display. Both single and double flowers are large and of fine substance. Among the former Canary, Hecla, Magnitude, Juliet, Proserpine, and Belona are conspicuous; and the most striking doubles are Eureka, White Lady, Defiance, Miss Lennard, Harmony, The Bride, and Josephine. Palms and Ferns are used to advantage in the arrangement, which is elegant and tasteful.

The well-known Swanley firm of Messrs. Cannell & Sons show an effective exhibit, comprised of Gloxinias, Begonias, Calceolarias, and Cannas. Among the former there are flowers of many delicate tints, conspicuous amongst which are *Petunias Duchess of York*, *Prince of Wales*, and *White Queen*. The Calceolarias are conspicuous for large flowers and dwarf sturdy habit. Begonias, both single and double, are quite up to the reputation of the firm. A special word must be given to the Cannas, which are superb. Large flowers of varied colour crown the sturdy spikes, and among the most telling varieties are *Salmon Queen*, *Rosalind*, *Leon Vassiliere*, *Florence Vaughan*, *Duchess of York*, *Italia*, *Sunset*, *Glow*, *Aurore*, *P. J. Berkman*, *Pioneer*, *Paul Bruant*, *H. Irving*, *Paul Meylan*, and *Incendie*.

A fine exhibit of Ferns is staged by Messrs. J. Hill & Son, Edmonton. As a background there are fine specimens of *Asplenium caudatum* and *nidus-avis*, *Davallia fijiensis plumosa*, *Pteris tremula Smithiana*, *Adiantum cuneatum* and *formosum*, *Nephrolepis exaltata*, and others; and pleasingly arranged in front are *Adiantum cardiochlena*, *scutum*, *roseum*, *macrophyllum*, and *cuneatum grandiceps*. *Lygodium scandens*, the climbing Fern, is conspicuous; and among other forms are *Doryopteris palmata*, *Lastrea aristata variegata*, *Blechnum brasiliense*, *Asplenium ornatum*, and *Davallia tenuifolia stricta*.

Mr. L. De Smet Duvivier, Ghent, Belgium, exhibits a small collection of Anthuriums, containing several curious and many elegant varieties. Among those shown are *Prince Albert*, *Prince of Wales*, and *Baron Schröder*.

Messrs. R. & G. Cuthbert, Southgate, contribute a varied collection of Ghent and mollis Azaleas, many of which are very beautiful. This adjective is rightly used in describing Anthony Koster, a fine yellow form; Velasques, a charming white; Dr. Pasteur, Apellus, Chevalier de Reali, Baron Pycke, General Vetter, and Jeannette Siemens. *Azalea Daviesi* is a charming white and cream flower, and shows conspicuously at one end of the group.

Messrs. J. Veitch & Sons, Chelsea, make an effect with a superb collection of Crotons, which makes a pleasing contrast to the masses of flowers all round. All the plants show signs of good culture, and among the most telling varieties are *Queen Victoria*, *Flamingo*, *Aigburth Gem*, *Thomsoni*, *Albert Truffaut*, *Warreni*, *Sunshine*, *Johannis*, *Prince of Wales*, and *Reedi*. Interspersed among the plants are Maidenhair Ferns, which help in making a most effective arrangement.

Delicately coloured Japanese Maples are shown by Messrs. W. Fromow and Sons, Chiswick. Among these are dotted flowers of *Lilium Harrisii*, which add to the effect. Very elegant is the foliage of many of the varieties of *Acers*, conspicuously *A. dissectum palmatifidum*, *A. dissectum purpureum*, *A. palmatum tricolor*, and *A. palmatum variegatum*.

The Worcester Clematises have come to be looked upon as regular attendants at the Temple Show, and this year they are as striking as ever. Messrs. R. Smith & Co. have an exhibit equal to any of their former ones, and charming indeed are the superbly flowered specimens of *Madame Van Houtte*, *Countess of Lovelace*, *Enchantress*, *Blue Gem*, *Marie Lefebvre*, *Princess of Wales*, *Snow White*, *Jackmanni*, and *Madame Van Houtte*. Messrs. R. Smith's superb exhibit gives abundance of evidence of what can be done with Clematises in pots, and shows the superior qualities of these plants when well grown for decorative purposes.

Messrs. Kelway & Son, Langport, are exhibiting Pæonies and Pyrethrums in pots, which make an effect, though the beauty of the latter is not enhanced by the conspicuousness of the stakes. It is not often that herbaceous Pæonies are shown in pots, and the fine flowers of *Dorothy*, *Lady Lilian Ogle*, *Admiral Dewey*, *Chelandry*, *W. B. Yeats*, *Joan Seaton*, *Mrs. Geo. Bunyard*, and *Wei-Hai-Wei* are conspicuous in size and quality of the blooms. In another tent the firm fills a large space with cut flowers in pleasing variety. Among these is a beautiful crimson Tree Pæony *Julius Cæsar*, and another of darker tint bears the name of *Henry Irving*. *Jean de Reszke* is a pure white, and contrasts pleasingly with the surrounding brilliant colours. In addition to the Pæonies there are fine spikes of *Delphiniums*, showy *Amaryllis*, *Pyrethrums* in variety, and other herbaceous flowers.

A long expanse of tabling is occupied with the interesting exhibit of hardy flowers from Messrs. Barr & Sons, Covent Garden, who, as usual, make a brilliant display. Fine spikes of *Eremurus* are conspicuous, and are very attractive, showing above a bewildering mass of variety in floral beauty. Here is a little clump of *Centaurea cyanus Victoria*, with its small blue flowers. Further on a diminutive rockery contains much that is interesting, as many of the tiny flowers could not be shown under any other conditions. Further still is a bunch of fine Lily of the Valley named *Fortuna*, surrounded by hardy flowers of every description, and at the end of the collection are staged Tulips and Irises. Lovers of hardy flowers will find much to interest them in Messrs. Barr's superb exhibit, and it is impossible to give everything the attention they merit in a cursory glance.

Messrs. J. House & Son, Westbury-on-Trym, show a fine collection of Pansies and Violas. The latter are made up in sprays, but many of the former are in small pots, and among other varieties *Prince of Wales*, *Iona*, *Stophill Gem*, *Mrs. R. K. Mitchell*, *William Haig*, *White Empress*, and *A. J. Rowberry* are very charming.

Messrs. J. Peed & Sons have a large exhibit of Gloxinias tastefully arranged with Maidenhair Ferns. The habit of the plants is dwarf and sturdy, and the colours varied and pleasing. Among the named varieties *Mrs. John Peed*, *Mrs. W. Weaver*, *Mrs. G. W. Sawday*, *Jasper*, *Queen of My Heart*, *Princess of Wales*, *Petunia*, *Duchess of York*, *Beacon*, *John Peed*, *Majestic*, and *Ethel*, are worthy of mention.

Diminutive alpine and other hardy flowers are shown in the exhibit sent from Messrs. Paul & Sons' Cheshunt nurseries. Cannas are remarkably fine in flower, some of the best varieties being *Iona*, *Miss Elsie Perkins*, *Mosaic*, *Lady Faudel Phillips*, *Golden Shower*, *Distinction*, *Mr. James Bailey*, and *Comet*.

The space allotted to Mr. M. Prichard, Christchurch, Hants, is devoted to hardy flowers. Conspicuous in the group are *Pyrethrum Mrs. Bateman Brown*, *Geum miniatum*, *Irises* in variety, *Eremurus robustus*, var. *Elwesianus*. *Aquilegias* are shown in variety, as also are *Pyrethrums*, *Trollius*, *Gentianas*, *Saxifragas*, and *Phloxes*, the whole making up a fresh-looking and varied collection. The Jadoo Fibre Company have an exhibit of plants grown in Jadoo fibre.

Hardy flowers in profusion are shown by Mr. T. S. Ware, Tottenham, these occupying the end of one of the tents. Conspicuous in the exhibit is a fine spike of *Eremurus Elwesianus*, which is very attractive. The exhibit also contains *Irises* in variety, *Saxifragas*, *Aubrietias*, *Pyrethrums*, *Trilliums*, *Alyssums*, and many other hardy flowers shown to good advantage. The firm also makes a grand show with Begonias, mostly double, and all superior in size of flower and quality. Among those attracting most attention are *Duke of Kent*, *Beauty of Belgrove*, *Prince of Wales*, *Her Majesty*, *Triumph*, *Mrs. S. Pope*, *Eclipse*, *Mr. Dunbar Wood*, *Mr. James Portbury*, *Brilliant*, and *Rosebud*. The most telling singles are *Mrs. Sharp*, *Bexley White*, *Belle Cole*, *Muriel*, *Sunset*, and *marginata*.

A pleasing break amid masses of floral beauty is the group of Ferns shown by Mr. H. B. May, Edmonton. The variety is bewildering, and the collection interesting to all Fern lovers. One of the most beautiful Ferns in the exhibit is *Phlebodium Mayi*, which was honoured with a

first-class certificate. Attractive also are the fine specimens of *Adiantum scutum*, *Davallia fijiensis robusta*, *Asplenium nidus*, and *Pteris cretica* Mayi. Giant Elks-horns are dotted about, and in the complication of variety and character there is much in Mr. May's exhibit that cannot fail to interest.

Mr. William Sydenham shows how Pansies and Violas can be grown in the neighbourhood of Birmingham. There are Violas shown in designs, and as such they are very effective; and conspicuous are sprays of Violas Stephen, Mary Stuart, Charm, Rover, Blanche, William Tell, Lucy Franklin, and Pembroke.

Ferns in charming profusion are staged by Messrs. W. & J. Birkenhead, Sale. They are mostly in small pots, and display an endless variety. All are elegant, and many of the forms extremely graceful, comprising some rare varieties, as well as others that are better known. Under a glass case provided for their accommodation is an elegant assortment of Filmy Ferns in variety, and in the exhibit the firm fully maintains its high reputation as Fern growers.

Messrs. J. Backhouse & Son, York, have their usual tasty exhibit of hardy alpine peeping from the crevices of a diminutive artificial rockery, where they look very charming. There are pretty blue Gentianas, Saxifragas, Primulas, Orchises, Campanulas, Iberises, and many others showing their diminutive forms and pleasing tints of colour. The firm also shows a few Orchids interspersed with elegant foliage plants, the effect of which is very pleasing. Not the least interesting are the firm's hybrid Water Lilies, displaying variety in this now popular family. The exhibit, as a whole, is tastefully arranged and quite up to former efforts of the firm.

Cacti are shown in variety by Mr. G. J. Pritchard, Forest Gate, London, E. Among them there are many curious members of this family, showing their varying habits, and attracting much attention on the part of visitors. Mr. F. Perkins, Leamington, shows plants of a yellow Carnation Primrose Queen, which, however, lacks scent. This appears to be the only defect, as the variety is free and effective. Messrs. Geo. Jackman & Son have an effective group of hardy flowers, including Pæonies, Pyrethrums, Cytisuses, Lychnises, and Irises. The plants are not crowded, and the group altogether is a pleasing one.

Mr. Amos Perry, Winchmore Hill, has an exhibit of perennials, in which the flowers are a little packed. Many familiar hardy plants are noticeable, including Geums, Phloxes, Lupins, Campanulas, Irises, Anemones, and Aquilegias. Messrs. A. W. Young & Co., Stevenage, are represented by a mass of new double Zonal Pelargonium King of Denmark, a collection of hardy flowers, and *Lilium Harrisii*, and an exhibit of hardy alpine plants. The firm also shows plants of Gloxinias of a good strain, and bunches of Pansies, which are much too crowded to be effective. Messrs. F. Miller & Co., Fulham Road, London, have an interesting exhibit of *Mimulus*, *Mignonette*, Pansies, *Lobelia*, and single *Petunia*, which are very attractive.

Very choice are the hardy flowers from Messrs. R. Wallace & Co., Colchester. There are dwarf Lilies of the *Thunbergianum* types, hardy *Cypripediums*, Geums, showy *Hemerocallis*, diminutive *Calochortuses*, and *Watsonias*. *Lilium rubellum* is a beautiful flower, and gained a first-class certificate. Flowers of *Tulipa persica* are included in the exhibit, as also are *Ixias* in variety, Irises of various forms and variety, and many others. Messrs. Wallace's exhibits at the Temple are always interesting, and in this respect the one mentioned is no exception. Mr. J. Douglas, Great Bookham, has a small exhibit of Auriculas, amongst which Dean Hole, Salamis, Green Frog, In Memoriam, and Delphi.

From Messrs. Dicksons, Ltd., Chester, come plants of an elegant *Dracæna* called Kippsi, a variety apparently suitable for table decoration. Mr. A. Tulett sent plants of a new sport from the double Zonal Pelargonium V. Raspail. Mr. John Pigg, Royston, Herts, has plants of a new Fancy Pelargonium called Agnes Alma. Messrs. J. Laing & Son have a superb exhibit, comprising tuberous Begonias and Gloxinias. Among the latter both singles and doubles are well represented, the flowers being large and of excellent substance, while the plants are healthy and sturdy in habit. The same may be said of the Gloxinias, amongst which there is a diversity of striking colours.

Messrs. Jas. Veitch & Sons make a superb display with their Gloxinias. The flowers are large and effective in colour, comprising such varieties as Mars, Cygnet, Beacon, Modesty, Virginalis, Mona, Columbus, Cordelia, Seraph, and others. The firm also fills a large area with hybrid *Phyllocactus*. Very showy are the blooms of these plants, and amongst the most effective are Adonis, Dorian, Romeo, Cato, La Belle, Isabel Watson, Norma, and Agatha. Maidenhair Fern is used in the arrangement, which is very striking and showy.

Outside of the tents Mr. J. Russell, Richmond, has set up a collection of hardy foliage plants, including Acers, Ivies, and Euonymuses, which are very attractive. Messrs. J. Waterer & Sons, Ltd., also show a fine collection of Japanese Maples, including many of the best varieties.

The whole of the central staging in tent No. 1 is in the possession of Messrs. J. Carter & Co., High Holborn, who have a very striking miscellaneous exhibit. The table is arched over, the name of the firm being interwoven in the greenery. Beneath are examples of the firm's specialities, including amongst the flowers some beautiful Gloxinias, *Calceolarias*, Lilies, and *Petunias*, with Palms and Ferns. Peas, Tomatoes, and Cucumbers are conspicuous in the vegetable portion of the stand. The Anglo-Continental Guano Works, 30, Mark Lane, exhibit a group of Gloxinias, presumably grown with the aid of the guano. They are not of very great merit.

Mr. G. Edom's Tulips, from Epsom, are gorgeously beautiful to-day (Wednesday) but to-morrow it is probable that much of their beauty will have departed. There are breeder and rectified flowers of bybloemens,

bizarres, and roses. The form of the flowers is as a rule good, and the colours rich.

No one shows hardwooded plants in better condition than do Messrs. W. Balchin & Son, Hassocks, and their exhibit in the Temple is worthy of their reputation. Grandly flowered plants of *Browallia alata*, *Boronia serrulata*, *B. heterophylla*; *Ericas* *Spenceri*, *candidissima*, *Cavendishi*, *perspicua nana*, *ventricosa rosea*, and *v. magnifica*; *Leschenaultia biloba major*, and *Genetyllis tulipifera*, are in mass.

Mr. John Forbes, Howick, is known to all as an excellent grower of plants, and the stand he has arranged is just such as anyone would expect him to show. It is composed entirely of Carnation Yule Tide, and Violas and Pansies in variety.

Messrs. J. Cheal & Sons, Lowfield Nurseries, Crawley, are represented by an arrangement of plants on a rockery, in the composition of which is displayed much taste. At each end of the rockery are Rhododendrons, Violas, Irises, and Pæonies. Of the Violas the best are J. B. Riding, Iona, Annie King, Duchess of Fife, Mars, Countess of Hopetoun, The Mearns, Dawn of Day, Blue Gown, H. W. Stewart, and Lord Elcho.

Brightly beautiful are the Azalcas from Messrs. M. Koster & Sons, Boskoop, Holland. Unfortunately they are shown as cut trusses, placed very flat in boxes of moss. This greatly detracted from their appearance. The colours are rich, and the form of the flowers excellent. Messrs. Dicksons, Ltd., Chester, show the new tree Carnation, Duchess Consuelo, a fine yellow.

Mr. F. G. Foster, Brockhampton, Havant, staged a collection of Sweet Peas, which comprised a number of new varieties shown rather too thinly for the best effect. Very charming are Blanche Burpee, Waverley, Lady Mary Currie, Duchess of Sutherland, Royal Rose, Lady Nina Balfour Colonist, and Daybreak.

Messrs. Fisher, Son & Sibray, Ltd., Handsworth, Sheffield, occupy a considerable amount of space out of doors with a group of miscellaneous ornamental foliage plants. The examples shown are well grown, and include *Acers* *Leopoldi*, *polymorphum purpureum*, *linearilobum atro-purpureum*, *rufinerva*, *septemlobum elegans purpureum*, *reticulatum*, and *rubrifolium*; *Cornus siberica elegantissima*; *Quercus macrophylla* and *concordia*; *Betula purpurea*, several Irises, Weigelas, Euonymuses, and others.

Mr. V. N. Gauntlett, Redruth, is exhibiting in the gardens an extensive collection of Bamboos. There are several distinct forms, but the specimens are not in the best state for showing the graceful beauty of these plants. Messrs. Paul & Son, Cheshunt, show a bed of Bamboos out of doors. The plants are in capital condition. A few Rhododendron seedlings are also included in group.

DECORATIVE EXHIBITS.

The art of floral decoration is one that has advanced by leaps and bounds during recent years. At all large shows exhibits of floral designs attract much attention, as the brains of skilled decorators are continually inventing new features. Under canvas, in the Temple Gardens, there are at present works of art in the way of floral decoration, and many of our leading firms have put forward their best efforts. These never fail to please, and judging from the interest shown, particularly by the ladies, the exhibits of this character are not lacking in admirers.

The Women's Gardening Association, Sloane Street, have an exhibit comprised of bouquets and floral arrangements. Miss Edith Langton, Swanley, has a pretty table decoration formed of Spanish Irises and variegated Grasses; Mr. W. G. Parkin, Sheffield, shows a table decoration of Violas and other flowers; Miss Dalton, Ludgate Hill, London, shows floral decoration, as also does Miss F. West Bradley, Gipsy Hill, S.E.

Bouquets and wreaths are staged by Moyses Stevens, Belgravia, in the form of a lovely harp of Orchids and Narcissi. Baskets of pink Pæonies and *Lilium Harrisii*, and a beautiful wreath of choice flowers.

Mr. Seale, Sevenoaks, shows floral arrangements, including wreaths, crosses, and other designs of simple flowers and foliage. The decorations on either side are formed of the rarest and choicest of flowers, but Mr. Seale shows that simple flowers can with advantage be used for the same purpose. Very graceful and beautiful are the floral decorations staged by Messrs. Perkins & Son, Coventry. Huge shower bouquets of Orchids are exceedingly beautiful. Baskets of the same flowers, and others of Roses are perfect examples of taste and elegance, and quite equal to the wide reputation of the firm.

Mr. J. Prewett, Bayswater, has a most elegant table decoration formed of Fancy Pelargoniums and light foliage, the effect of which is very pleasing. Messrs. Jones & Sons, Shrewsbury, show a tasteful arrangement of flowers. Bouquets of Carnations, Orchids, and Violas are represented, as well as baskets of Sweet Peas, Roses, and Irises, all set up to good advantage. Mr. L. H. Calcutt, Stoke Newington, shows a magnificent decoration composed of Orchids, Lilies, and greenery, in a large epergne surrounded by smaller arrangements of Marguerites, Spanish Irises, Cornflower, and Ferns. The exhibit shows not only the beauty of the flowers, but also the suitability of the stands for table decoration.

A charming display is made by Messrs. B. S. Williams & Son, Piccadilly and Holloway. There is a beautiful and gigantic basket of Orchids, a basket of large Carnations, a mirror surrounded with white Narcissus, lightened with delicately tinted Orchids. One bouquet is a mass of scarlet Geraniums and Anthuriums, another is a dream of Lily of the Valley, white Roses, and Odontoglots, and in all the florists' art is fully displayed.

CERTIFICATES AND AWARDS OF MERIT.

Aculypha Sanderi (F. Sander & Co.).—This is a plant that will prove of the greatest decorative value. It can be had in a dwarf state or as standards, and is equally floriferous in both forms. The bright rose spikes are from 12 to 15 inches long and about three-quarters of an inch in diameter. The spikes are produced from the axils of the leaves. (first-class certificate).

Anthurium Scherzerianum Senateur Montiflore Leves (De Smet Duvier).—This is a superb variety with a medium-sized spathe of a cream colour spotted heavily with brilliant scarlet (award of merit).

Apple Ontario (Bunyard & Co.).—An American variety of handsome appearance. It is of large size and very distinctly ribbed. The eye is open and deeply set in a furrowed basin. The stalk is long and deeply inserted. It partakes largely of the character of the old Maltster (award of merit).

Auricula Snowdrop (R. Dean).—This is a double white flowered Auricula, and is very striking. The flowers are of good size and pure white in colour (award of merit).

Begonia Mrs. Dunbar Wood (T. S. Ware).—A beautiful double-flowered variety of good shape; the colour is rich apricot (award of merit).

Caladium L'Ami Schwartz (F. Sander & Co.).—A most distinct Caladium. The leaves are broad at the base and have a sharp point. There is a margin of green all round the leaf (award of merit).

Caladium Guaratinguetor (J. Laing & Sons).—A handsome crimson-scarlet variety, with edging of dark green (award of merit).

Cattleya Fernand Denis (Charlesworth & Co.).—This is a hybrid from a cross between *C. Acklandiae* and *C. gigas*. The narrow rose coloured sepals have deeper rose spots at the tip, which are absent from the broad rose hued petals. The crimson lip is of immense width, and has a cream coloured patch in front of the pink throat (first-class certificate).

Cattleya Mendeli Oakes Ames (H. Low & Co.).—A superb variety, marvellously rich in colour. The sepals and petals are rich rose, the latter having a bright crimson patch on the tips. The handsome lip is velvety maroon crimson. The throat is yellow, with crimson veins (first-class certificate).

Cattleya Mendeli Mrs. E. V. Low (H. Low & Co.).—For form and substance this Mendeli must take a high place. The colour of sepals and petals is very pale blush. The broad lip is crimson with white fimbriations, and a bright yellow throat (award of merit).

Dendrobium Dalhousianum Salmoena (H. Low & Co.).—This can best be described as a very pale buff form of the well-known type. It is said to be the only variety known (first-class certificate).

Eremurus Elwesianus (T. S. Ware).—This is a superb Eremurus. The spike of pale salmon rose-coloured flowers is about 6 feet high (award of merit).

Holly Golden King (Little & Ballantyne).—A very handsome Holly, that will certainly attain to great popularity. The leaves are large, bright green in the centre when young, deepening with age, and with a bright golden edge. The plant is of very vigorous habit (award of merit).

Licuala Jemenceyi (F. Sander & Co.).—A Palm that ought to be of value, as the leaves are of a bright green colour, and the habit of the plant is good (first-class certificate).

Laelio-Cattleya intermedia flava Golden Gem (Charlesworth & Co.).—This is a lovely variety. The sepals and petals are rich yellow, as is the inner portion of the throat. The front lobe a peculiar shade of orange crimson (award of merit).

Laelio-Cattleya Admiral Dewey (Charlesworth & Co.).—A bigeneric hybrid, resulting from a cross between *Cattleya Warneri formosa* and *Laelia elegans Mastersi*. The flower is very handsome. The prevailing colour is rich purplish rose, the broad lip being bright crimson (first-class certificate).

Lilium rubellum (R. Wallace & Co.). One of the most distinct Liliums in cultivation. The colour is pale pink, and the trumpet short and widely expanded (first-class certificate).

Mitonia vexillaria Empress Victoria Augusta (Baekhouse & Son).—A brilliant-coloured variety. The broad lip is very intense rose, the basal portion being pure white. The sepals and petals are also pure rose (award of merit).

Mitonia Bleiana rosea gigantea (Jules Hye).—An immense flower, of which the prevailing colour is white, faint flushed with rose on the lip. The sepals also are slightly tinged, while the petals are deep purplish rose at the base (award of merit).

Odontoglossum crispum × *Harryanum* (C. Vuylsteke).—A hybrid, of which the parentage is not given. The cream coloured sepals and petals are almost wholly brown at the base. The broad lip is cream at the front, with brown blotches and spots at the base (first-class certificate).

Odontoglossum Charlesianum (A. Madoux).—This is a charming Orchid, of which the ground colour throughout is cream, and the abundant spots and blotches bright brown (award of merit).

Odontoglossum crispum decorum (L. Linden).—In form this crispum promises well. The blotch of bright chocolate on the petals and the mass of similarly coloured spots on the sepals are very fine. The lip is of good form (award of merit).

Odontoglossum Pescatorei bellatulum (L. Linden).—Though the flowers are somewhat starry, this variety is very beautiful on account of the brilliance of maroon patch on the sepals and the spots on the petals and lip (award of merit).

Odontoglossum crispum zebrinum (L. Linden).—A lovely variety. The

cream coloured base is spotted, blotched, and barred with crimson brown (award of merit).

Odontoglossum venustum (L. Linden).—The cream ground colour of this handsome *Odontoglossum* is almost obscured by the bright brown of the spots on the petals, lip and upper sepal, and the bars and blotches on the lower sepals (first-class certificate).

Pæony Julius Caesar (Kelway & Son).—A superb variety of the tree section. The colour is an intense crimson (award of merit).

Pæony Henry Irving (Kelway & Son).—This, too, is of the tree section; the colour is deep blackish crimson (award of merit).

Pæony Jean de Reszke (Kelway & Son).—The large flowers of this splendid *Pæony* are pure white (award of merit).

Phlebodium Maji (H. B. May).—This is a superb Fern that has the appearance of being a seedling from glaucum. The fronds are handsomely divided, and of a glaucous grey hue, except at the tips, which are green (first-class certificate).

Phyllocactus Epirus (J. Veitch & Sons).—A rich scarlet variety of great size, and with a glow of purple in the central portion of the flower (award of merit).

Phyllocactus Agatha (J. Veitch & Sons).—Pale salmon is the shade of this splendid variety. The flower is very large (award of merit).

Rose Aurora (W. Paul & Son).—A Hybrid Tea of the first quality. The flower is large and very full, and the colour rich salmon. It is a free bloomer (award of merit).

FRUIT AND VEGETABLES.

With the exception of the remarkable exhibits of fruit of Leopold de Rothschild, Esq., and Messrs. T. Rivers & Son, which are arranged in the chief marquee, the collections to be referred to are displayed in one of the long tents over the terrace walk, next the Thames Embankment. While there are remarkable exhibits of both fruits and vegetables, also groups, in which both are combined, we doubt if, in the aggregate, the display is larger than in previous years.

FRUIT.

In this section the three primary exhibits are those from Gunnersbury House, Sawbridgeworth, and Maidstone. The exhibit of Leopold de Rothschild, Esq., is a remarkable one. Mr. Hudson seems to have represented a viney in bearing and a miniature orchard house under canvas. Vines bearing excellent crops of Grapes are trained under the roof of the marquee, and beneath them are groups of heavily laden Cherry, Plum, Peach, Nectarine, and Fig trees to the number of about forty. In front of these are fourteen boxes of gathered fruit. Early Rivers Nectarines are of remarkable size, six fruits weighing 3 lbs. 3 ozs. Auguste Nicaise Strawberries are enormous, and the white fruits of Louis Gautier conspicuous. Cherries in six varieties are very fine. The entire exhibit is such as has not been previously arranged by a private gardener.

The exhibit of Messrs. T. Rivers & Son consists of about forty trees of the splendid Early Rivers Nectarine, some of the older of these being laden with brilliant fruit, while trees only one year in pots are each bearing one or two splendid Nectarines, testifying to the early productiveness of the variety, combined with the most satisfactory growth. The smaller and earlier Nectarine, Cardinal, could not be represented, as the crops were cleared a fortnight ago. Included in the collection under notice are *Crimson Galande*, *Early York*, and *Hale's Early Peaches*; also trees of the *Stint Plum*, which is rising in public favour, and the better known *Rivers' Early Prolific*. The trees are in the best of condition, and will uphold the cultural fame of Sawbridgeworth.

A very striking collection of seventy dishes of Apples and Pears, by Messrs. George Bunyard & Co., attracts much attention. The table is made the more interesting by small heavily bearing Pear and Fig trees in pots. Among the Apples so fine and firm are *Calville Rouge*, *Bismarck*, *Lane's Prince Albert*, *Newton Wonder*, *Tibbit's Pearmain*, *Lord Derby*, *Annie Elizabeth*, and *Ontario*, a large, roundish, angular variety, which received an award of merit for its tenderness and good quality. Mr. George Bunyard, the active head of the Maidstone Nurseries, not only knows how to grow fruit, but to "keep" Apples and show them in a manner not yet equalled at this season of the year.

A highly meritorious collection of under glass fruit mainly is displayed by Mr. J. McIndoe from Hutton Hall. It includes excellent Grapes Melons, Oranges, Black Tartarian Cherries (splendid), Peaches, Nectarines, Figs, Pears, Apples, and Strawberries, supplemented by Tomatoes and Vegetable Marrows, all in superb condition.

Mr. G. Featherby exhibits, from the Vineries, Gillingham, Kent, excellent Black Hamburg Grapes, *Hale's Early Peaches*, *Dryden Nectarines*, as well as Tomatoes, Cucumbers, and a market basket of French Beans. Mr. J. Ryder, The Gardens, Hawkhurst, St. Albans, exhibits good and remarkably well coloured *Grosse Mignonne Peaches*.

Large Melons are contributed by Mr. E. Beckett, Aldenham, and smaller by Mr. T. Richardson, Hollingbourne, and Royal Sovereign Strawberries by Mr. J. Miller, Ruxley Lodge, Esher.

VEGETABLES.

Exhibits are not numerous, but some of them are very large, important, and interesting. A ponderous collection is effectively arranged by Mr. E. Beckett, gardener to Lord Aldenham. It comprises some eighty dishes, including enormous Leeks, large piles of Cabbage

and Broccoli, excellent Potatoes, Tomatoes, French Beans, Vegetable Marrows, Globe Artichokes, Asparagus, Peas, young Turnips, and Carrots, Mushrooms, and all kinds of salads. Everything displays superior culture, and the group is highly meritorious.

Still larger and very different is a marvellous display provided by Mr. W. Empson, gardener to Mrs. Wingfield, Ampthill. Some visitors indeed considered it too large, as involving an extensive duplication of varieties. Be that as it may, it covers some 24 yards in length of tabling, and is like bringing a kitchen garden into the tent, with its rows of Peas, Kidney Beans, and Tomatoes in full bearing, and in front of them piles of practically all kinds of vegetables which the garden affords at this season of the year—all bearing the stamp of good culture.

Mr. W. Hayes, gardener to the Marquis of Northampton, Castle Ashby, stages some forty dishes of well-grown produce, similar in kinds and character to those already enumerated, the Asparagus being the finest we observed in the exhibition. Very fine Asparagus is exhibited by Mr. Frank Chapman, 57, Crouch Street, Colchester, but excelled, except in one huge bunch, by the Castle Ashby produce, with its greater length of succulent green stems.

Boxes and clusters of large Mushrooms are staged by Messrs. Mount Bros., Willow Farm, Canterbury; also enormous clusters of almost milkwhite buttons and broilers, with spawn bricks, by Mr. E. Addy, Ealing Road, Brentford.

Mr. S. Mortimer, Rowledge, exhibits nine boxes of Tomatoes, also eight boxes of Cucumbers, some in a green, others in a ripe or seeding state. Very handsome are the fruits of Sutton's A1. The smaller new variety, Sensation, attracts attention, as does a new dark, prominently spined form, called "The Keeper," with stems showing its great productiveness.

Messrs. Jas. Carter & Co., at one end of their great festooned exhibit of plants and flowers, have a fine pile of Model Cucumbers, as well as Peas, Climbing French Beans, and Tomatoes, including heavily borne plants of Duke of York.

The greatest advance in vegetables, however, is represented in the remarkable exhibit of new early Marrowfat Peas, by Messrs. Sutton and Sons. The varieties are not shown in dishes, but flat baskets, of half a bushel each or more of splendid large pods. The varieties include Sutton's Seedling, Early Giant (handsome pods), A1, Bountiful, and Empress of India. Alternately with the baskets of Peas are fine fruits of choice Cucumbers—Sutton's A1, Matchless, Peerless, and Pride of the Market, as well as smaller fruits of the continuous bearing "Everyday." Relief is afforded to the substantial exhibits by elegant Palms, small Ferns, and a margin of Selaginellas—an altogether excellent display.

Mr. Graham Powell, Horticultural College, Swanley, has a bold, effective, and creditable exhibit of Cucumbers in pots, trained umbrella fashion, the pots being hidden by Peas in pots bearing profusely. Between the elevations different kinds of vegetables are represented, the whole making an attractive display.

Mr. W. L. Bastin, gardener to Alex. Henderson, Esq., Buscot Park, has an attractive mixed exhibit of Palms, Potatoes, Melons, Tomatoes, Cucumbers, and French Beans—bright and attractive.

A novelty in the vegetable line is provided in the form of small, well blanched, crisp looking heads of "White Forcing Celery." They are necessarily small, and have presumably been grown in frames; but all the same, tempting by their young green leafage. Exhibited by Mr. John Nicholls, Tooting.

MEDALS AND CUPS AWARDED.

GOLD MEDALS.—Sir Trevor Lawrence, Bart., for Orchids; Messrs. W. Paul & Son and G. Mount for Roses; J. Veitch & Sons for Caladiums, Crotons, &c.; and Leopold de Rothschild, Esq., for pot fruit trees.

SILVER CUPS.—Messrs. Jackman & Son and R. Smith & Co. for Clematis; Messrs. Barr & Son for herbaceous plants; Cutbush & Son for foliage plants, &c.; Sir Frederick Wigan, Charlesworth & Co., Hugh Low & Co., F. Sander & Co., H. S. Leon, Earl Percy, L. Linden, and J. Cypher for Orchids; Mr. J. R. Box for Begonias; Mr. C. Turner for Roses and Pelargoniums; Lord Aldenham and Sutton & Sons for vegetables; Sir J. Pease for fruit; and Messrs. T. Rivers & Son for pot fruit trees; Carter & Co. for vegetables; and Cannell & Son for Begonias, &c.

SILVER-GILT KNIGHTIAN MEDALS.—Messrs. Bunyard & Co. for Apples; Mrs. Wingfield for vegetables; and Mr. Mortimer for Tomatoes and Cucumbers.

SILVER-GILT FLORA MEDALS.—Mr. T. S. Ware for herbaceous plants; Messrs. Perkins & Son for floral decoration; Mr. H. B. May for Ferns; Messrs. B. S. Williams & Son for Orchids and decorations; Messrs. Lewis & Co. for Orchids; W. Thompson, Esq., for Orchids; Mr. Jules Hye for Orchids; Leopold De Rothschild, Esq., for Carnations; Messrs. W. Balchin & Son for hardwooded plants; Messrs. James & Son for Calceolarias; Messrs. Fisher, Son, & Sibray for foliage plants; Messrs. Kelway & Son for Pæonies, &c.; Messrs. J. Laing and Sons for Gloxinias, &c.; Messrs. J. Peed & Son for Caladiums; and Mr. J. Waterer for Rhododendrons.

SILVER-GILT BANKSIAN MEDALS.—L. Mond, Esq., for Orchids; Mr. H. J. Jones for Begonias; Messrs. F. Cant & Co. and Mr. W. Rumsey for Roses; Messrs. Backhouse & Co. for hardy plants; Mr. G. Edom for Tulips; Mr. J. Pritchard for Cacti; Mr. M. V. Seale for decoration; Messrs. J. Hill & Son and Messrs. W. & J. Birkenhead for Ferns; M. S. Cooke, Esq., for Orchids; and Mr. L. De Smet Davivier for Anthuriums.

SILVER KNIGHTIAN MEDALS.—The Marquis of Northampton and the Swanley College for vegetables; and Mr. G. Featherby for fruit.

SILVER FLORA MEDALS.—Messrs. J. House & Son for Violas; Messrs. A. Young & Co. for Gloxinias; Mr. A. Perry for herbaceous plants; Mr. M. Stevens for bouquets, &c.; Mr. W. Sydenham for Violas; Mr. L. Calcutt, Mr. J. Prewett, and Messrs. Jones & Sons for floral decorations; Mr. J. Russell for Azaleas; Mr. M. Prichard for herbaceous plants; Messrs. F. Miller & Co. for Mignonette, &c.; Mr. F. Chapman for Asparagus; Mr. W. Godfrey for Asparagus; Lord Foley for

FIG. 83.—RAMBLER ROSE PSYCHE. (See page 444.)

Strawberries; Mr. A. Henderson for fruit and vegetables; Mr. W. Lawrence for Asparagus; Messrs. R. & G. Cuthbert for Azaleas; Messrs. Fromow & Son for Maples; Mr. W. Iceton for foliage plants; Jadoo, Ltd., for plants; Messrs. Cripps & Co. for Maples; and Messrs. J. Cheal and Son for hardy plants.

SILVER BANKSIAN MEDALS.—Mr. M. Koster for Azaleas; Mr. Tulett for Zonal Pelargoniums; and Mr. E. G. Reid for Rhododendrons.

An exhibition of this character, it almost goes without saying, could not be prepared for and conducted in the absence of a large amount of forethought and of devoted work, and therefore recognition is due for services rendered by the Secretary (Mr. Wilks), Superintendent (Mr. Wright), and all who have striven so willingly and well to make it as successful as the shows of previous years.

WEATHER IN LONDON.—The weather in the Metropolis during the past seven days has been very changeable. On Thursday and Friday it was wet almost the whole of the day, but on Saturday it was brilliantly fine and very warm. Sunday was wet in the morning, but clear later, while on Monday afternoon a little thunder was heard, and the air was close, as was it throughout Tuesday. On Wednesday, at the time of going to press, it was dull yet dry.

— **WEATHER IN THE NORTH.**—The weather has again been very variable during the past week. On the morning of the 18th there were between 2° and 3° of frost, and there was a recurrence of frost on the following morning. Several days were bright; but generally a cold easterly wind has prevailed, and rain has frequently fallen.—B. D., *S. Perthshire*.

— **GARDENING APPOINTMENT.**—Mr. W. Pilgrim, foreman at Hackwood Park, Basingstoke, has been appointed gardener to Sir George Meyrick, Bart., Bodorgan, Anglesey, N. Wales.

— **VAGARIES OF PRIMROSES.**—I am greatly obliged to "St. Albans" for his kindly note (page 430). The writer, however, has never met me at Shipley, as he suggests, as I never was there. Possibly there may be another "A. D." in the world who is a little less notorious. Why does "St. Albans" vary his botanical nomenclature of the common Primrose by calling it in one place *Primula acaulis* and in the other *P. vulgaris*? The term *acaulis* is one of doubtful correctness, but is sometimes applied to the double-flowered section. The Cowslip is *P. veris*, and a red form is *P. veris rubra*, whilst the true Oxlip is usually called *P. elatior*. Still it is just possible that the Oxlip is but a large coloured form of the Cowslip. There can be no doubt but that the variation in the colour of the flowers of the wild Primroses "St. Albans" mentions was due to the presence in the soil of iron, or some similar chemical or mineral ingredient. But soils of that description are rare, and their influence on Primulaceæ more rare. That it is not permanent is evidenced by "St. Albans" when he tells us that whilst seedlings of these plants growing in the same soil gave coloured flowers, those that were planted or naturally grew on the grass plot, not having similar soil, but one doubtless devoid of iron, reverted to their pristine hue of sulphur. Doubtless the cause of variation in colour found in this case applies in every similar case. I have seen tens of thousands of wild Primroses transferred to ordinary soils, such as that of the Thames Valley for instance, and have never seen any colour variation on the flowers in after years. That is, I think, general experience.—A. D.

— **WHAT WILL THE SUMMER BE?**—Writing under the depressing influence of a pouring wet day, perhaps I am for that reason unduly pessimistic in assuming that we shall, or may, have a wet, cold summer. I do not assume that because we are having a wet and rather cold May, but I fear it because a wet summer is practically due. No one can wish such a result, because did it come it would be in many ways a national calamity. Of course we have had wet, cold summers, before. Those who are specially observant, and note carefully the nature of each season, could tell us, no doubt, very accurately how many wet summers we have had during the past twenty years, and even the average of wet ones for the now fast-passing nineteenth century. Mr. Edward Mawley could, no doubt, give on that point much useful information, and perhaps he could also give his opinion as to the probable nature of the weather for the coming summer. In entering into any speculations as to probabilities, we must not forget that a considerable rainfall was due to us ere the month of May began. During this month a good deal has been done to equalise matters, although the balance is probably yet on the dry side. But Nature is commonly very erratic, and often so far from being content to indulge in comparative balancing, rushes into extremes, and either burns us up with long-continued drought, or floods us with excessive rains. Our ideal weather and season is found when balances are evenly adjusted. But if the rain should presently cease and fine weather follow, then should we be entitled to look for a year of marvellous production. So far, what the weather will be a week, a month, or a year hence is enshrouded under a veil we cannot lift.—AN OLD GARDENER.

— **CALCEOLARIAS AT READING.**—A correspondent informs us that there is a more than usually fine display of these gorgeous early summer flowers in the establishment of Messrs. Sutton & Sons on the outskirts of the town. As the result of continuous striving for higher excellence, the home exhibition is said to be better than ever, and worth a long journey to see.

ROSE PSYCHE.—This is a new Polyantha Rose that was raised by Mr. G. Paul, jun., of the firm of Messrs. Paul & Son, Cheshunt, from a cross between *Crimson Rambler* and *Bennett's Golden Fairy*. It was shown at the Drill Hall on April 26th, when the Floral Committee of the Royal Horticultural Society gave it an award of merit. As may be seen in the illustration (fig. 83, page 443), it partakes largely of the character of the *Crimson Rambler*, but is not perhaps quite so strong in growth. This, however, may be changed in the course of a few seasons. If such prove to be the case we are of the opinion that a modicum of the extraordinary popularity which has been accorded to *Crimson Rambler* will be passed on to its progeny. *Psyche* is very floriferous, and the individual flowers are of good size and substance, the colour being pale rose pink.

— **ROYAL METEOROLOGICAL SOCIETY.**—The monthly meeting of this Society was held on Wednesday afternoon, the 18th inst., at the rooms of the Royal Astronomical Society, Burlington House. Mr. F. C. Bayard, L.L.M., President, in the chair. Mr. R. H. Scott, F.R.S., read a paper on the frequency of rainy days in the British Islands. He had taken the number of rainy days in each month at forty stations for the twenty years, 1876-95, and then divided that number by the total number of days in the month, and so ascertained the resulting percentage. The greatest excess of frequency is always on the extreme north and west coasts. June is the month with the least number of rainy days, but in July the summer maximum of rain occurs, bringing the well-known Lammas floods. In October the weather becomes decidedly showery, and the distribution begins to assume its winter type. November is the month with the greatest frequency of rainy days. Mr. F. J. Brodie read a paper on the abnormal weather of January last, which was one of the most remarkable winter months on record. The month was singularly dry, with an absence of snow or sleet—a somewhat unusual feature in January, even for any individual station, but far more remarkable as applying to the country as a whole. The special feature, however, was the striking absence of severe frosts, the frequent prevalence of unusually mild weather, and, as a result, the abnormal warmth of the month, especially in the more northern parts of the kingdom. The mean temperature was generally, over the whole country, about 5° above the average, while at many places situated in the more northern parts of the kingdom it was more than 6° above the average.

— **THE R.H.S. AUTUMN FRUIT SHOW.**—We have received the schedule of the Exhibition, which will open at the Crystal Palace on September 20th and close on October 1st. In addition to the usual classes for gardeners and nurserymen, with substantial money prizes for the former, cups and medals for the latter, two new sections are provided—one of substantial importance, the other an interesting experiment. The first of these sections is for market gardeners only, forty prizes being offered in twenty classes for the packing of different kinds of fruit for market that are in use at the time of the show. The prizes range from £2 to 10s, and an instructive display should be forthcoming. The next new section is entitled "Special district county prizes" in two classes—(A) Apples, six dishes, distinct, four cooking and two dessert; (B) Dessert Pears, six dishes, distinct. The prizes offered are—first, £1; second, 15s., in ten classes, the first open only to Kent growers. Seven others to groups of counties (specified), as, for example, "Open only to growers in Surrey, Sussex, Hants, Dorset, Somerset, Devon, and Cornwall;" and so on throughout England and Wales, with a class each for growers in Scotland and growers in Ireland. A similar plan was projected and carried out in connection with the Great Show in the London Guildhall in 1890. The R.H.S., however, goes a step in advance in offering to add third-class single fares to prizewinners from their nearest railway station to London. It must not, after this, be said there is no enterprise in the premier Society, or that it does not offer inducements to provincial growers to compete at its shows. These classes are open to "gardeners and amateurs only," and growers of good fruit in the different counties may now turn their attention to what will undoubtedly be by far the greatest fruit show of the year. We have heard, but hope the rumour is not true, that these shows are not likely to be continued if there is not an increase in the subscriptions. The published list is certainly far short of the sum expected—£100, the number of subscribers being less than fifty; but more, it is hoped, may follow, and save what is really a great national fruit show from extinction.

SPATHOGLOTTIS AUREO-VEILLARDII.

THIS charming hybrid, of which the varietal name tells the parentage, was exhibited at the Drill Hall by Messrs. J. Veitch and Sons, Ltd., Chelsea, on the 10th inst., and elicited a considerable amount of admiration. The flower is of the most refined type of beauty, and well merited the first-class certificate which the Orchid Committee awarded to it. The ground colour of the sepals and petals is deep creamy yellow, while over the whole of the latter organs, which are considerably broader than the sepals, there are immense numbers of rose-coloured pin-head spots that add materially to the flowers' charm. At the apex of the sepals the spots again occur, but are here so minute as to almost appear like a flush of colour. On page 439 we give a woodcut (fig. 82) of this *Spathoglottis*, which is one of the latest examples of Mr. Seden's skill as a hybridist of Orchids.

LÆLIA LATONA.

Though one of the older raised hybrids this is certainly one of the most beautiful, and as it is easily grown, and has been freely propagated, there is every prospect of it becoming in future a popular garden Orchid. The celebrated Chelsea firm has given us many fine things in the way of hybrid Orchids, but few finer than this. It is the progeny of *L. cinnabarina* and *L. purpurata*, the former being the seed-bearing parent, and the one that shows most strongly in the hybrid. Its influence is plainly seen in the flowers, and especially, also, in the base of the pseudo-bulb, these being rounded and swollen like those of *L. cinnabarina*. Several flowers are produced upon a spike, and they are individually about 5 inches across; the sepals and petals are a light tawny orange, the lip narrow, of a distinct and pretty shade of reddish purple margined with orange, and finely undulating. It was first exhibited in 1892 before the Orchid Committee of the Royal Horticultural Society, and at the last meeting at the Drill Hall Messrs. Veitch had several fine well-flowered plants in their group.—H. R. R.

ORCHIDS ROUND LONDON.

FOR the past few years I have made it a practice to visit the several collections of Orchids in and around London. True, it has not been found possible to make an inspection of the whole of them, but the best use was made of the time at disposal. This season it is proposed to go over some of the ground again, and to record the features of the several establishments, both private and professional, that will be visited. The Orchids will not be examined from the point of view of a botanist, and no technical descriptions will be given—indeed, the endeavour will be made to regard them from a popular aspect; so far as can be done, while preserving correctness of nomenclature and doing justice to the plants seen. Probably no better period of the year than this could be chosen, for on every hand plants are flowering, and the species, hybrids and varieties of all kinds are well nigh endless.

There can be no doubt that within a radius of about thirty miles of London are grown some of the finest Orchids in the country, and it is equally beyond question that the most valuable individual collection is within that area. Look to the north, south, east and west of the metropolis, and actually within the four-mile radius of Charing Cross, and Orchid growers of world-wide repute will be found. Some are growers for trade purposes, others collect the plants purely as a hobby, and a most fascinating hobby it is, while a few combine these two objects. Happily, too, the number of growers is increasing, and some who only a few years ago commenced their culture, are now, by liberal yet judicious purchasing, standing in the front rank. No one, I think, would care to give even an approximate opinion as to the value of the Orchids grown by these several enthusiasts, but it must amount to many scores of thousands of pounds.

It must not be thought that because the provincial collections are not included in these notes they are not considered worthy of attention. Such is not the case, for many of them are extensive and rich in quality, but the facilities for their examination are greater for those residing in the various neighbourhoods than they are to a Londoner. The task, therefore, is deputed to the many others who are doubtless perfectly familiar with the best collections in the country.

Returning to our own immediate province, the difficulty of knowing where to start presents itself. They cannot be taken alphabetically, while it is equally impracticable to centralise them into

districts, as it were. Let us start this week in London, and end—well, where and when we can. Having decided upon a metropolitan collection for the opening notes, the journey will be a short one, for it will lead us to Chelsea.

THE ROYAL EXOTIC NURSERY.

Just when Messrs. J. Veitch & Sons commenced the culture of Orchids, and with how many plants they started, I am not prepared to say, but that they have now, at Chelsea and at Langley, a splendidly representative collection, no one will deny. One may go at any time to the great nursery in King's Road and some Orchids will be found in flower, though at one period there may be only a few, while at another time there will be many. Two weeks before the great show that is now being held in the Temple Gardens was opened, this visit was paid, and in every house were numerous flowers, many of extraordinary merit. Hundreds of plants were at the zenith of their beauty, while hundreds of others had yet to produce their spikes and expand their blooms. There were cool, intermediate, and warm house kinds, and a few of them will be noted in the succeeding paragraphs.

In many establishments it is the practice to concentrate as much as is possible all the Orchids in flower in one or two structures, but such is not the case at Chelsea. If the visitor be desirous of seeing all the flowers he must pass from one structure to another, until every house that is devoted to Orchids has been seen. In some houses flowers will be comparatively scarce, perhaps, but in the majority a diversified display will be found. Of the general good health of the plants it is unnecessary to enlarge at length, as all are in such good condition—indeed, considering the surrounding atmosphere, they are remarkably creditable both to the firm and to Mr. Harris, the grower. Of course numbers are brought from Langley when they are in flower, but by far the larger proportion find a home at Chelsea from the time of importation until they pass into other collections.

As was anticipated, the first house that is entered from the long walk, and which is devoted mainly to *Odontoglossums*, was very charming, for there were many varieties of crispum to see. There was a marked absence of really inferior forms, though it is superfluous to say that some were far better than others. Many other species were observed, but to name them would occupy more space than is available in the Temple Show issue. Leaving this structure we enter one slightly warmer, where *Cypripediums* in variety are always in bloom and ever interesting. Hanging from the roof was the fragrant and chaste *Burlingtonia pubescens*, while contiguous to it *Cœlogyne tomentosa*, with its rosy buff flowers, and on a plant of *C. Dayana* fifteen long pendulous spikes were observed. They were a pleasing change from the brighter flowers of *Oncidium ampliatum majus*, *sarcodes*, and others that were flowering so profusely.

The Orchid fernery in this nursery is always cool, pleasant, and refreshing, for from the soft green of Ferns and the brown of the stones the Orchids rise in graceful beauty. Plants of *Oncidium Marshallianum*, with splendid spikes of bright flowers, and several varieties of *Cymbidium* produced a charming display that was much enhanced by superb specimens of *Thunia alba Dodsoni*, with its refined flowers, and *Epidendrum Wallisi* in unique condition. *Dendrobiums*, *Bifrenarias*, *Odontoglossums*, *Lycastes*, and others all lent charm and diversity to this section of the Orchid department; but we must not linger, for the entrance to the great *Cattleya* house is reached, and we must glance within.

Cattleyas, *Lælias*, *Vandas*, and a few others occupy the whole of the space available in the immense structure known to all orchidists as the *Cattleya* house. It is a grand house, and none but plants of the best merit should find a home therein. They need not all be in flower, but they ought to exhibit the best characteristics of health in plump pseudo-bulbs and deep green, tough foliage. Such as a matter of fact are the prevailing features of the plants now to be seen, but added to these points there are scores in full flower. Hundreds of flower sheaths of various *Cattleyas* are showing, the forms of *Mossiae* especially being, owing to the absence of sun, rather later than is customary. A day or two of bright sunshine, however, will alter their appearance, and flowers will be opening on every side as well with these as with *Lælias* in variety.

Of those now expanded several forms of *Schröderæ* are very beautiful, as are the many plants of the handsome *C. Lawrenceana*. Of *C. Wellsiana* there are three forms—namely, the type, *C. W. albida*, and *C. W. langleyensis*, of which the latter is superb, and received an award of merit at a recent meeting of the Royal Horticultural Society. Specimens of *C. Mendeli* are numerous and of merit, as are those of *Lælia purpurata*. *Lælia elegans* is a lovely flower, and is here seen to perfection, and the same may well be said of *L. Latona* and *L. Hippolyta*. These are only a few of the many that are to be seen in bloom, but they must suffice for the time being. Ere turning, however, to other

places, we would congratulate Mr. Harris on the condition of the plants and on the cleanliness that prevails throughout the Orchid department.

SUNNINGDALE PARK.

Let us now go further afield. This journey to Sunningdale Park recalls vividly to mind the last occasion on which we had the pleasure of meeting Mr. F. J. Thorne at home. I remember well that it was on a hot July day, two years back, when a start was made from London to Englefield Green, to see Baron Schröder's Orchids, whence a walk of four miles or so across Windsor Park brought us to Sunningdale. This time the route was altered, and the latter was placed first, with the object of driving to The Dell. The plan was carried out successfully, and instead of being broiled in the sun it was a case of being drenched in the rain. The fortune of war, it may be said—well, it was accepted with resignation, and both collections of Orchids were seen, with one or two other things almost, if not quite, as interesting.

The invitation from Mr. Thorne to "come to breakfast" was accepted literally, and we (for I had a companion) arrived at the gardens about 9.30. Entering beneath Mrs. Thorne's arch of Roses and Clematis montana, the latter in full bloom, and having accepted hospitality, we turned with continued pleasure to other matters. Major Joicey's Orchids are remarkable for quality far more than they are for quantity—indeed, so far as mere numbers are concerned it is surpassed by many, but in the excellence of the culture none is before it. House space is all too limited for the grand plants that are grown, but the deep and practical interest taken in their culture by Mrs. Joicey and Mr. Joicey, jun., as well as the Major, augurs well for future extensions. There can be no question, judging from the condition of the stock now held, that the grower will rise with any developments that may come.

At the present moment the plants of *Odontoglossum* (*Miltonia*) *vexillarium*, of which there are nearly 100, are making the brightest display. Small plants and large are producing spikes of from seven to fifteen handsome, shapely flowers of varying shades. The leaves are quite as good as the flowers, for they glow with the rich hue of health. Two sides of a span-roofed house are devoted to them, and no plants could occupy the space with greater credit to both owner and grower. These are a specialty of Mr. Thorne's, which other *Odontoglossums*, such as forms of *crispum*, are not. Yet the latter are admirably cultivated and produce hard foliage and flowers of good form and substance. *O. hastilabium* was observed in splendid condition, as was *Houlletia tigrina* in the same house.

Foremost in this collection, from a purely cultural point of view, ought to be placed *Diacrium* (*Epidendrum*) *bicornutum*, to which reference was made by a correspondent in the *Journal* on April 21st last. Several of the plants there adverted to are still in flower. Then, too, *Anguloas* are grand, particularly conspicuous being a plant of *Ruckeri sanguinea*, producing several twin-flowered scapes. In addition to the few which it is here possible to enumerate, there are some capital *Cattleyas*, *Lælias*, *Oncidiums*, *Sobralias*, *Dendrobiums*, *Coelogynes*, *Masdevallias*, with several rarer Orchids of chiefly botanical interest, and an excellent stock of *Cypripediums*, comprising species and varieties of more than average merit. As an example of this, it is only necessary to name Major Joicey's variety of *Exul*, which received from the Royal Horticultural Society a first-class certificate, and was figured in the *Journal of Horticulture* for April 9th, 1896.

Like most other orchidists, the Sunningdale grower has become bitten with the fever for hybridisation, and scores of his "babies" are to be seen on every hand. The labels tell of interesting crosses that have from time to time been made, and it can only be hoped that the strenuous efforts that have been made will be rewarded with success. The secrets of the splendid results that have been attained to by Mr. Thorne he considers as studying the natural habitats of the plants, and copying them as closely as possible, with perfect cleanliness of plants, pots, and structures. These points are so simple that everyone ought to be able to copy them, and doubtless they would be rewarded for their efforts.

THE DELL.

As has been said, the drive to The Dell was made in pouring rain, but we were more than rewarded by the sight of the Orchids and the welcome accorded by both Mr. H. Ballantyne and his skilful grower Mr. Clarke. Where such a collection of Orchids as that which is here seen can be found it would be difficult to say, and in some respects it cannot be disputed that Baron Schröder's stock is unrivalled. Probably no individual gentleman has been so assiduous as the Baron in collating all that is rare and good in the Orchid world, and his success is nothing short of remarkable. But his generous monetary outlay would have availed him little had he not had skilful practical support. This was forthcoming in every respect from Mr. Ballantine and Mr. Clarke, the latter of whom acted as guide through the houses.

Not one or two, but many of The Dell Orchids are unique, and their value cannot be estimated. This is more especially the case in the *Odontoglossum crispum* section. One has but to think of the half dozen varieties named *Baroness Schröder*, *apitum*, *Stevensi*, *Starlight*, *nobilis*, and *Ballantinei* to realise the rarity of the collection, though neither these nor a score of others that could readily be enumerated can convey any idea of the grand results that are secured by good culture. Splendid spikes carrying upwards of a dozen flowers are abundant, while others with over a score of flowers are not uncommon. Another extraordinary point is the extent to which varieties improve at The Dell. For example, *O. c. Starlight* procured a year ago is far superior in all respects to the flowers shown by Mr. R. Brooman White of Ardarroch.

Dendrobiums are now making a very beautiful display, especially such as *Farmeri*, *thyrsiflorum* in variety, and others. The plants are very healthy and the flowers peculiarly rich in colour. *Vanda teres*, though not yet in full bloom, is very promising, and the few in flower are of excellent quality. *Odontoglossum* species and hybrids, with *Miltonia vexillaria*, are seen on every hand, as are *Oncidiums*, some of which are in flower and some in bud. The spikes on these are of immense length and substance. In various houses is a superb assortment of *Cypripediums*, including *callosum* *Sanderæ*, *Hyeatum*, *Stonei* and *Stonei platytænium*, the white *bellatulum*, and grand forms of several of the better known kinds. *Sobralias*, *Aërides*, *Saccolabiums*, *Cochlioda Noezliana*, *Maxillarias*, *Masdevallias*, *Anguloas*, *Calanthes*, and *Coelogynes* are met with in force as the houses are traversed, and almost without exception their condition is good.

Another feature is the stock of *Cattleyas*, *Lælias*, and *Lælio-Cattleyas*, which is nothing short of wonderful in its extent and variety. Many of the *Cattleyas* here, as elsewhere this season, are somewhat later, but the splendid plants will be resplendent in the course of a very few days. Of those in flower, *C. intermedia alba*, *C. Skinneri alba*, forms of *Mendeli*, and others are very beautiful, and of themselves are well worth seeing. Add to these the *Lælias purpurata* and *Latona*, with *Lælio-Cattleya Digbyana Mossiæ*, and a conception may be formed of the present condition of affairs. There are many hundreds of plants of all sizes, from the tiniest seedling to the specimen 2 or 3 feet through, and all appear to revel in the treatment that is meted out to them by the grower.

The structures at The Dell devoted to Orchids, as well as those occupied by fruit trees and flowering and foliage plants, are all capitally built for the purpose, and the arrangement of them is in all respects admirable. They vary in height and shape, some being lofty, and others very low, according to the requirements of the plants within them. Not only are the woodwork and glass kept scrupulously clean, but the floors, stages, and pots also receive proper attention, while, it is needless to say, the plants themselves are never neglected. But no more must now be said, for both time and space are exhausted. In a future issue reference will be made to other collections of Orchids which are so well represented at this moment in the Temple Show.—H. J. WRIGHT.

A "RECORD" CLUSTER OF BANANAS.

THE enclosed photograph shows a remarkable bunch of Bananas (*Musa Cavendishi*) grown by Mr. F. Jordan, head gardener to John Corbett, Esq., Impney, Droitwich. The bunch measured 3 feet 9 inches from the top "fingers" or pods to the bottom one, and it weighed 114 lbs. when cut. It contained 283 "fingers," all of very good size and uniformly disposed from top to bottom. The sucker was planted on January 15th, 1897, and showed fruit on the 27th last September, consequently the fruit has been developed during the dark and cold days of winter chiefly. Mr. Corbett was so pleased with the bunch that he had it photographed. It was weighed in the presence of several men, and the figures given are correct. The stem of the plant girthed 36 inches.

Impney Gardens are in the highest condition under the fostering care of Mr. Jordan, and the owner encourages him by ungrudging liberality. The collection of plants has been materially enlarged (including a small but choice selection of Orchids), and a large span-roofed house, 100 feet by 12 feet, is being erected for their accommodation.

Mr. Corbett continues his benefactions to the town of Droitwich by the building of a new hotel (the Park Hotel), replete with every convenience and thoroughly homely. It is surrounded by about 6 acres of ornamental and dressed grounds, with a charming lake, and has a direct outlook upon the beautiful park, which was laid out by Mr. Davis. Mr. Jordan has been engaged in laying out the grounds surrounding the new hotel, and has to generally supervise the park in addition to his

charge at Impney, which shows that his situation is not exactly a sinecure. Mr. Corbett has proved his entire satisfaction with his gardener in the most tangible manner possible; long may that satisfaction continue.—J. UDALE.

¶ We are very much obliged to Mr. Udale for sending the splendid

exceeded by 7 lbs. by a bunch grown by Mr. D. McKenzie at Sherwood Park. Mr. Corbett and his gardener are to be congratulated on the noble specimen now illustrated, and which we are sorry to learn could not be kept for the Temple Show. Some of the fingers which we measured and weighed were 9 inches long by 6 inches in circumference:

FIG. 84.—MUSA CAVENDISHI AT IMPNEY—WEIGHT 114 LBS.

photo of, so far as we know, the heaviest bunch of *Musa Cavendishi* on record. The heaviest cluster we have seen was grown by Mr. J. Ollerhead, gardener to Sir Henry W. Peek, Bart., at Wimbledon House, in 1877, and exhibited at a meeting of the Royal Horticultural Society. Its weight was 98 lbs., and its merit was recognised by the award of a gold medal; but, according to the "Gardeners' Chronicle," this weight was

they turned the scale at $6\frac{1}{2}$ ozs., and a "twin" weighed 12 ozs. As may be seen in the illustration, they were wonderfully uniform in size, and we can testify were of distinctly superior quality. We have heard of heavier clusters of *Musa sapientum*, but have no precise records, and shall be glad if they can be furnished. Mr. Corbett's handsome bunch is the heaviest of *M. Cavendishi* that has been brought to our notice.]

CHRYSANTHEMUMS IN MAY.

Is it not a very extraordinary thing that the Chrysanthemum Mutual Friend should be in flower now, and quite a rarity? I should be glad to know if any of your readers have experience of a midseason variety flowering at this time of year. The old plant was cut down in late autumn after flowering, and threw up two stems, which each now bears a bloom equal to any midseason flower.—CHARLES FUTCHER, *Amateur Grower*.

DWARF CHRYSANTHEMUMS.

THERE are two methods of producing dwarf Chrysanthemums which will give fair-sized flowers in November. Dwarf plants are of great utility, not only to the exhibitor constructing a group, but to those who have to furnish an attractive display for the conservatory, and to the amateur having only a low-roofed house in which to flower his plants.

The method of securing dwarf plants most commonly adopted is to grow a number of suitable varieties in the ordinary way from cuttings rooted during the winter months, confining them to a single stem without any pinching or stopping whatever. Encourage a strong, sturdy growth until the middle or end of May, when preparations must be made for propagation. Prepare the 2½-inch pots and soil before taking the cuttings, which require to be inserted as fresh as possible. Place one crock at the bottom of each, and over that some rough material riddled from the compost. The latter should be equal parts of turfy loam and leaf soil, with a fair proportion of silver sand and a little crushed charcoal, well mixed together. Use it moist, filling the pots to the rim, then shake or press it down firmly, surfacing with fine sand. The upper 3 inches of a strong plant makes the best cutting, but it is desirable in most cases to cut lower, and form the cutting to the most convenient length afterwards. The cut-down plant will, properly treated, break into growth, forming several strong growths at the upper part of the stem, from which, when advanced enough, a selection of not more than four to be retained should be made.

In preparing the cuttings, cut transversely below a joint, removing the bottom pair of leaves. Insert firmly in the middle of the pots, give a good watering, and stand them in a frame that has a slight bottom heat. Keep the cuttings close and shaded from the sun until rooted. Immediately this has taken place, which will be seen by the cuttings extending in length, take them out into a cooler frame, where they can be close to the glass and have more air. All may not be ready for this treatment at one time, but it is important that those which are be taken out before lengthening too much. If afforded judicious airing and watering the pots will soon become full of roots, when a shift will be necessary into 3½-inch pots, and finally into 5 and 6-inch pots.

Another excellent method of obtaining good dwarf plants differs from the last, inasmuch as the cuttings are secured from old stock plants retained for the purpose. They are wintered in as cool a temperature as possible, the growths being thinned to a few of the best. The plants after severe frosts are past have sheltered outdoor treatment, which maintains the growths stocky and strong, and cuttings may be obtained better than from young plants. Propagate at the same time, affording the treatment throughout recommended for the others.

The beheaded young plants, after they have started into growth, require to be put into their flowering pots. These plants will form dwarf, bushy specimens, capable of carrying from four to twelve flowers, the latter when terminals are allowed.

Many cultivators depend alone on this latter method of producing comparatively dwarf plants, but it follows that the dwarfest must be produced by late-rooted cuttings; but these cannot perfect satisfactorily more than one flower. Constant and unremitting attention is necessary in the cultivation of Chrysanthemums generally, but more especially so in the case of vigorous-rooted plants, such as even the dwarfest ought to be, growing in small pots. Successful results are not achieved unless the plants are grown in the full sun, which necessitates constant attention to watering, never allowing the plants to flag if possible. In very hot weather it is a good plan to protect the pots from the sun by leaning a board against them. The plants should stand on moisture-retaining materials. When the pots are filled with roots a regular system of feeding must be adopted. Manurial applications, however, ought not to be given when the soil is dry. Well moisten the soil first with clean water, then any nourishment applied will be better absorbed, readily assimilated, and not so easily lost.

It is chiefly the Japanese varieties which give the best results as dwarf plants. A selection of all or some of the following varieties may be cultivated, as most of them are free growers, and produce large blooms. C. Davis, C. H. Payne, Etoile de Lyon, Golden Gate, Lady Hanham, Lady E. Saunders, L. Brooke, Madame Carnot, Madame Gustave Henry, Mlle. Lacroix, Mons. Chenon de Leché, Niveus, Pallanza, Pride of Maidenhead, Rose Wynne, Souvenir de Petite Amie, Vivian Morel, Col. Smith, W. H. Lincoln, and W. Holmes.—E. D. S.

VENTILATING VINERIES.

ON page 404, May 12th, of the *Journal of Horticulture*, Mr. Wm. Taylor of Bath gives some interesting notes on the temperatures of one of his vineries and his mode of ventilating the same on a given day (May 9th last), and asks me how the top ventilation theory would work in such a case, and what I would have done had I been in his place. Well, the first thing I am certain I ought to have done was to thank the Lord for such a fine warm May day, and that my lines were cast in such a favoured place as Bath.

Here in the north we have recently had quite a little May blizzard. On Wednesday morning, May 11th, the hills were white with snow. The following morning we had some frost. Friday morning 5°, Saturday morning 10°, with ice as thick as a penny, a bitter cold wind varying from the N.E. to N.W. blowing from hills from 2000 to 3000 feet high about ten miles off. The outside shade temperature has seldom risen to 50° up to the 16th inst., even with strong sunshine, of which we have had a good deal. Add this to coals up 2s. 6d. per ton lately, could you blame me envying Mr. Taylor in his "warm Bath?"

In fairness to the weather, however, I must admit that with the exception of the cold snap alluded to, we have had a very fine spring, and the country and crops are looking exceptionally well and promising. From this Mr. Taylor might conclude that my remarks on top ventilation applied only to Scotland. As he has had no practical experience further north than Liverpool, I have had none further south than county Durham; but over that area I know that front ventilation is a standard rule of practice, and believe that were it the exception and not the rule, it would be to the benefit of the Vines and plants grown; and I cannot see why this should not also apply to all England. There might be some exceptions, such as the position of the houses, their construction, or an exceptionally warm locality such as Mr. Taylor evidently enjoys at Bath, but even in his case less front ventilation than he has been using might be an advantage.

No one could find fault with his method of ventilating on the day stated. He did not open the front sashes until 12 noon, and the temperature 86°. This, he tells us, was a departure from his usual practice, which evidently is to admit more front air at an earlier period of the day, and before the temperature rises so high. Had he done this on the day in question, the practice, to my mind, would have been faulty; and though I would not say it would have done harm on such a fine day, it was not necessary, and its non-use, even for a limited time, was a step in the right direction. We cannot always rely on a thermometer for the correct shade temperature, either out of doors or inside a vinery. It depends very much when, and how it is placed, and whether the roof is wholly or only partly covered with foliage.

It might not be advisable in all cases to suddenly change the conditions a plant has been grown in, even in the matter of air. It is best to begin new practice with new growth. Plants, like individuals, have a knack of adapting themselves to circumstances. I regret that at this busy season I cannot go more fully into this subject. It is one that might be discussed with profit to all concerned. I trust others may give their opinions and practice. It would be interesting to hear from some who grow Grapes in the sunny south without the use of front air.

I have long known Mr. Taylor through the pages of the *Journal* as one of our foremost Grape-growers, and more than once have admired his fine exhibits of Grapes. His remark, "That he is not too old to learn," shows the right spirit. It is the spirit we all—old and young—should have in seeking to add to our knowledge in anything pertaining to our profession.

Mr. Taylor would like to know the construction and angle of our vineries. When building we are not particular to have them at a certain pitch. What little knowledge I ever had of geometry has got rather rusty. With the aid of a riddle to draw a circle on a potting bench, and a bevelled square, I find the angle to be much the same as Mr. Taylor's house, about 35°. One lean-to with a short 4 feet hip at the back is much flatter than this. This house is 285 feet long by 20 feet wide, facing S.S.E. Ventilation is by a continuous board on one side of the ridge only, which, when open to its full extent, is only 12 inches. It lifts in six sections. This house has a considerable rise, 16 feet in the whole length. The ventilator at the top end is opened much earlier, and freer than those further down. The bottom one has only been opened on three occasions this season, and that only about an inch. The roof runs to 1 foot from the ground at the front.

Another house is span-roofed, running north and south, 300 feet long and 20 feet wide, depth of sides 2 feet, ventilated with a continuous board on one side of the ridge only. Being built on the level ground it requires even airing all over. Up to the first week in May the ventilators were not once opened in this house, and since, with the exception of one day, have not been more than 3 inches up. This house has a more airy and exposed position than the others. The

house described in my lecture is a low span, running north and south, with a sunk path in centre, 150 long by 15 wide, 18 inches deep at the sides. It is ventilated the same as the others, but with this difference, that the board is not continuous, opening two sashes and missing one; 2 inches is the most the ventilators have been opened in this house up till now (May 16th).

I may say that the roofs are glazed with foreign glass, 13 inches wide. We do not trouble much with thermometers in the houses, but I know that on no day this season has the temperature exceeded 90°. —D. BUCHANAN, *Forth Vineyards, Kippen*.

[Very different are the surrounding conditions of the vineries in charge of Mr. W. Taylor and those of Messrs. D & W. Buchanan. There appears to be, by comparison, an extreme of exposure in the one case and of shelter in the other. A warmer air bath we could not very well imagine than in and around Mr. Chaffin's structures, which nestle at the foot of a southern tree and shrub clad declivity, trees also affording shelter, if we remember rightly, from the east and west. It is a veritable sun trap, and an ideal spot, we should imagine, for "red spider." The Kippen ventilators would be inadequate for the vineries at Bath.]

"SILVER LEAF" IN PEACH TREE.

THE shoots submitted by "Gardener," on page 434, last week, were similar in appearance to many Plum leaves, and commonly regarded as due to the action of frost. In the case now in question the trees were grown under glass, and instead of Plum the affected leaves were of Peaches. Everyone growing Peaches against walls, especially in elevated and cold districts, knows the only too familiar "blister," and its being mostly, if not entirely, confined to outdoor trees. Few attribute it to anything but cold winds, particularly easterly, inasmuch as protection and warmth prevent to a great extent attack by the blister fungus. That is the general opinion of gardeners, but is not fully endorsed by fungologists.

So far as I know "silver leaf" has not been observed on Peach trees outdoors, or on Plum trees under glass. The affection may be found on Portugal Laurels occasionally, the trees ultimately collapsing or losing their leaves. This has been attributed to fungus at the roots. I have examined many specimens of "silver leaf," from Sloe up to Green Gage Plum, from Bird Cherry (*Cerasus padus*) up to Bigarreau Napoleon Cherry, and down again to Portugal Laurels, but have not been able to detect any parasitic micro-organism. Similar result has attended the scrutiny of Birch and Hornbeam leaves affected with "silver leaf" until browned. Why? Perhaps this case of "silver leaf" in Peach leaves may afford a clue.

The shoots of Peach trees, now to be referred to, were cut from "a house facing east and standing on limestone, the fruits setting well, but falling off before they attain any size." The leaves are quite silvery on the upper surface, a fair sample being shown in the illustration, fig. 85, at A, and on the under side pale or yellowish green. Beyond the "silver" there was nothing abnormal about them—no malformation, swollen, distorted, thickened, twisted, or curled parts. A section through the tissue revealed nothing beyond the normal form (B). The "silver" was but skin deep (a), epidermal cells somewhat more contracted than usual (b), and those underlying considerably rounder than ordinary (c). No fungoid hypha presented itself, the intercellular spaces being quite free from foreign bodies. This might be attributed to faulty ventilation. Well, I have seen many instances of bad air-giving, but never any producing "silver leaf" in any plant under glass.

Upon further examination I noticed that some of the leaves had brown spots on them, and one leaf in particular was dead at its extremity, being curled up, as injured tissues and dead parts usually are. I thought it a mere cause of water having hung on the leaf and destroyed the part, but the browning ran into the "silver," and had the appearance shown at C. Making a section where the brown joined the silver, the tissues were seen as represented at D. The silver epidermis (d) was tinged with yellow; beneath the cuticle and inner surface were minute yeast-like bodies (e), and these prevailed the intercellular spaces of the subjacent cells (f). The slice was from the upper surface or silver side of the leaf.

Turning the leaf over the under side, shown at E, had the yellowish green hue before mentioned, and on the brown part a sprinkling of white bloom. This was the very thing I had striven to find for years. Bodies were seen on the slide, and at once recognised as *Ascomyces* species, as had also been the mycelial hyphæ. A section gave the result shown at F. It was regarded as a form only of Peach leaf blister fungus (*Ascomyces deformans*), but there was no deformed living leaf, no blister, swelling, or anything of that kind, merely the silver leaf, and where the fruits appeared a browning and destruction of the tissues.

The ascus (g) contains eight spores, and these are liberated by an opening (h). In many cases, however, the spores germinate in the ascus, producing buds or conidia, and then appear many-spored. The discharged spores (i) soon germinate and produce secondary spores, like yeast, by gemmation or budding (G).

I offer no explanation of the phenomena, suffice to state the facts as observed and leave others to speculate. It may be remarked, however, that the case is very distinct from leaf-blisters, but the fungus is practically the same. The mycelial hypha is pushed beneath the cuticle and the epidermis, and the nutritive or vegetative hypha runs or buds between

the formative cells of the host-plant, abstracting their contents and utilising their substance to purposes of its own.

The fungus does not (at least this form of it) blister the leaves, but appears the same as that found sometimes on the browned foliage of "bird's nests" or "witches' besoms" in Plum, Cherry, and Bird Cherry, and the blister form is the "bladder" found on young fruits of those trees, known as "bladder-plum" fungus (*Ascomyces pruni*). A very closely allied species causes silver leaf in *Potentillas*, but yellowish spots also appear, and on these "fruits" (*A. potentillæ*) are produced.

The mycelium of the parasite spreads through the intercellular spaces of the tissues of young shoots in the spring, being perennial, but how it can give rise to "silver leaf" passes my understanding, the suppression of the chlorophyll on the upper surface of the leaf and not lower, or only to a limited extent, being more a chemical than organic characteristic. In

G, spores producing secondary growths by gemmation (budding), enlarged 520 diameters.

the case of some Plums the silver or cuticle covering peels off, and it also occurs with various other plants that have been damaged by an overdose of tobacco or nicotine, a new one being formed. I must, however, leave the matter for the research which the subject merits, theory being of little use without facts.—G. ABBEY.

THE LATE MR. GLADSTONE.

QUITE fitting and appropriate is it that a record of the death on the morning of the 19th inst., of the greatest commoner of the century should be inscribed in these pages, of which, as far as his multifarious duties allowed, he was a reader. An instance of the keen discernment of Mr. Gladstone may be mentioned. About ten years ago we published a short note, the first of its kind that appeared in our columns over a period of forty years, describing an example of success in transforming barren Pear trees into productive Apple trees by grafting. Detecting the note, and foreseeing, as the deceased gentleman thought, a practical method of improving our fruit supply, he cited the case in one of his famous speeches. While knowing of instances of success in establishing Apples on Pear stocks, we could not regard them as more than facts of an interesting nature, and so stated at the time. Mr. Gladstone was unquestionably anxious to develop what he called "small cultures." In turning to one of his post-cards we find these words:—

"As regards this small culture in its many branches, I am more and more of opinion that, though in each particular detail the results might appear secondary, the aggregate effect would be a great benefit to our agriculturists, and if we could also gain a still greater increase in the supply of milk, be a most valuable boon to the health and comfort of our population."

Many will remember Mr. Gladstone's advocacy of the culture of small fruit for conversion into jam, which caused some persons to smile and others to plant. He subsequently said: "While the world at large will have plenty of appetite for the consumption of all the jam that is made, British agriculture must depend, not on the smaller but the larger culture—upon the production of great staples on which mankind must live, because though jam is a very good thing, yet mankind could not live upon jam."

Fruit culture was really advocated as a home pursuit worthy of extension, as an adjunct to, not as a substitute for, the usual farm crops. Mr. Gladstone was firm in his belief that the course advised was prudent, for he subsequently wrote to us the following sentence:—"I shall be much gratified if I can truly think that I have been instrumental in drawing increased attention to the subject of fruit growing in this country." That the deceased gentleman was largely instrumental in effecting such extension there cannot be a doubt.

Though Mr. Gladstone did not desire that his death should be followed by tributes of flowers, which he perhaps feared would be overwhelming, he wore them during his life on all great occasions, a favourite being thought to be a white Rose; yet on the presentation of the usual bouquet, when attending the opera, on being asked which really was his favourite, he is said to have replied, "There are so many beautiful flowers that I really don't know."

The great and good man—and people of all shades of opinion admit he was both—left behind him flowers of rhetoric and good counsel which will, perhaps, never die. We cull one over which some of our young friends may well ponder:—"Do not believe those who too lightly say that nothing succeeds like success. Effort—honest, manful, humble effort—succeeds by its reflected action upon character, especially in youth, better than success."

Setting aside contentious politics absolutely, it will be granted by reflecting minds that the world has been made better by the long life and happy, peaceful death of Mr. William Ewart Gladstone.

NOTES ON BOUVARDIAS.

NOT many years since these beautiful plants were considered by many persons difficult to manage, but of late years their requirements have been better understood. They are now amongst the most popular and useful plants of the day, and when well grown are unsurpassed by anything in the same way. Evidence of this is not wanting when we hear of some of our large market growers cultivating them by the thousand; one firm alone, a few years ago, annually grew about 40,000 plants for cutting and general decorative purposes. But, apart from the great value of the Bouvardia from a market grower's point of view, how seldom do we find a garden, even of medium size, without its stock (large or small) of plants which are so admirably adapted for bouquet and buttonhole work?

Stove treatment is usually accorded, but the best results I have seen attained followed the plan of growing Bouvardias without any artificial heat throughout the summer and autumn months. I am speaking from a private grower's point of view when recommending this cool system, as doubtless large growers find it advantageous to accord them stove treatment. Last summer we grew a number in cold frames (this I think preferable to exposing them to the elements). The plants were potted in 48's in March, and by the end of April they were transferred to 24's, keeping them growing steadily and pinching as required to induce stocky growth. At the middle of the month of May they were plunged in ashes in cold frames, and kept partially closed for a few days to give them a good start, afterwards removing the lights, which were only replaced to throw off excessive rains. As the plants advanced in growth they received applications of liquid manure with benefit, and occasionally a slight dressing of an approved artificial fertiliser.

The compost used consisted of equal parts of peat and loam, and half a part leaf soil and sand. If the cultivator is desirous of turning his plants out of the pots, this will be found a good mixture, especially if ample drainage is provided. I have practised both methods, and I am in favour of retaining them in the pots for obvious reasons—viz., the plants may remain out much later in the season, and receive no check when the inclement weather compels us to house them. So long as the weather is favourable they should remain, for I have made note of the fact that the autumn dews are highly beneficial to the Bouvardia. In the event of the cultivator requiring the plants in bloom early in the season, of course they should be taken in sooner. Another point in favour of retaining them in the pots is, that as the plants advance in growth (which will be very rapid when they are once established) the frames may be raised with bricks at the bottom, so that the lights may be put on without danger of bending or breaking the young shoots. This will also allow the air to pass through the frames freely, and will assist in ripening the wood. From the luxuriant health of our plants last summer, and the profusion of bloom which they bore for several months, I am convinced that the system is much the best for the private gardener.

A temperature of about 50° to 60° should be accorded the plants when housed, and the applications of liquid manure continued until well in bloom. A damp close atmosphere at this period must be avoided, and great care should be exercised in watering, not to give them too much. Syringing in bright weather is essential to keep down insects. Mealy bug, red spider, and thrips are very partial to the foliage, but with pure air and clean water few of these enemies will make their appearance, and if they do, no difficulty will be found in keeping them in check.

Cuttings of the young shoots, when about 2 inches in length, will root

freely in the spring if inserted in sandy soil, covered with a bell-glass, and plunged in the bed of the propagating pit. These should, when well rooted, be potted into thumb pots and placed on a shelf in an intermediate house, afterwards stopping and shifting them as required. By the following spring these will be well-established plants, suitable for growing by the method described above. The most valuable of all the Bouvardias is *B. longiflora*, which bears large pure white fragrant flowers, whilst of the smaller flowered varieties especial mention may be made of Alfred Neuner, Dazzler, Hogarth, President Garfield, and Vreelandi.—H. T. M., Stoneleigh.

TAMWORTH PANSY AND VIOLA SHOW.

MAY 21ST.

IT was anticipated that as this popular show, which was held in the attractive grounds of Mr. Wm. Sydenham at Bolehall House, was dated to take place a week earlier than customary would somewhat militate against a good display, especially with the unpropitious weather which has recently prevailed, would be somewhat inferior. Such a fear, however, was not fully realised, though owing to the showery weather on the day of the show the attendance of visitors was not so large as usual. The number of exhibits, however, was fully as high as those of previous exhibitions. The quality of the flowers was on the whole good, as also was that afforded by the splendid assortment distributed over the pleasure grounds and nursery. Another pleasing feature was the profusion of *Scilla campanulata* luxuriating beneath the groves of tall trees skirting a portion of the grounds, in striking contrast to the adjacent wide borders containing thousands of bushy plants of the charming and exceedingly floriferous Viola Mrs. J. Donnelly with its bluish white self-coloured flowers intermixed with lines of the Poet's Narcissus. In the flower garden alone in front of the residence large beds of various coloured Violas served to complete the picture.

A feature in the large exhibition tent were the table decorations and other designs, such as wreaths, crosses, harps, and lyres, and for which, in addition to the first prize of 2 guineas for a dinner table decoration, valuable prizes were offered and worthily gained. The successful exhibitors of dinner table decorations were Mrs. Lovatt, Mr. W. B. Crane, Mr. J. M. Johnston, and Mr. John Smellie an extra prize, in the order named. Mr. Robert Sydenham, Birmingham, contributed (not for competition) an attractive table, composed chiefly of double and single Poets' Narcissi, Spanish Irises, and Carnation Uriah Pike. The competition table exhibits were severally composed of Pansies and Violas, with ornamental foliage, such as Ferns and Asparagus. It may here be remarked that in Mr. Smellie's exhibit a grand seedling "Fancy" Pansy named Miss Neil was awarded a first-class certificate. It has a dense rich purple blotch, edged with white; top petals crimson, double edged, shading off to pale yellow, and slightly striped edging. The three blooms were much admired, as also was another seedling named William Gardiner, a unique variety of large size and substance, rich cream top petals, crimson shading, dark purple blotch.

A first-class certificate was awarded to a curious little Violette, of quite a new type, exhibited by Mr. W. Sydenham, named Tom Thumb. It is an exquisite Viola for the rockery, or as a dwarf border edging. It is a rayed rich yellow, and as exhibited in spray fashion looked charming. Amongst other striking varieties of Violas noticeable in Mr. Sydenham's collections, arranged as sprays, places of honour must be given to Stephen, a deep yellow rayed and a greatly improved Bullion, with a good habit, eclipsing even the beautiful Pembroke; whilst such charming varieties as Devonshire Cream, Florizel, Pembroke, Blanche, Formidable, Althea, Kitty Hay, Lady Franklin, Masterpiece, Amy Barr, Rover, Lark, and Mrs. Wm. Greenwood, a canary yellow self, formed a complement of great beauty and excellence.

Reverting to the competitive exhibits, of which space will not allow of detail, mention may be made of the meritorious designs in Pansies and Violas contributed by Miss Johnston, Miss E. Sydenham, and Messrs. J. M. Johnston and J. Smellie, all being distinguished by excellence of artistic taste. In the various classes for blooms of Fancy Pansies and sprays of Violas, Mr. W. Maxwell of Glasgow took the lion's share of prizes, his sprays being set up on sloping stands of various shapes, covered with black velvet, thus reflecting the flowers to great advantage.

Amongst other exhibitors and prizetakers were Mr. James Maxwell; Mr. Egan, Belfast; Mr. Leonard Brown, Brentwood; Mr. Fowler, Freasley Hall, Tamworth; Mr. Pearson, Newport; Mr. Howell, Oxford; Mr. Stevens, Wilnecote, and Mr. T. Nadin, Alnecote, who exhibited more or less in the cut bloom classes. Altogether the show of exhibits was a success, and was considered to be one of the best of its kind yet held at Tamworth.

DOUBLE GORSE.—For about three months during spring and early summer masses of this plant make a glorious sight, every branch being smothered with golden blossoms. For gardens, or where cover is needed in parks and other places, it has decided advantages over the type, as it is a dwarfer and more compact grower, and after flowering, instead of seed pods, there is a mass of bright green shoots. Anyone who has a few plants can quickly raise a stock by inserting cuttings of half-ripened wood in a bed of sandy soil in a cold frame during August, keeping the frame closed and shaded until roots are formed. When rooted, they should be potted and kept in the pots until they can be planted in permanent quarters.—W. D.

THE YOUNG GARDENERS' DOMAIN.

HARDY FRUITS AND THEIR CULTURE.

IN my opinion nothing can be more interesting or of so much importance to young gardeners as the study of hardy fruits and their culture. Where every attention is given to fruit culture under glass we find, as a rule, first-class produce; but in the hardy fruit garden we get almost the reverse, simply because the trees do not get one-half the attention they so well deserve. This is proved by the fact that where a gardener does take an interest in hardy fruits, we see plainly that by perseverance he can produce a good sample of fruit, which is admired by all who have the pleasure of visiting his fruit garden. I am well aware that in many localities the soil is not suitable for the cultivation of fruit in its present condition, but much may be done by improving the soil and making it suitable for fruit trees in future.

Where it is desirable to improve the soil, should it be too wet, stiff and clayey, the first essential part of the work will be to have it drained in a thoroughly practical manner. For the improvement of the soil, a time must be chosen when it is at its driest, autumn, I think, being preferable, as it may then be left in a rough state through the winter. It should be trenched about 2 feet deep, and a quantity of lime, soot, and wood ashes be thoroughly incorporated with the surface soil. Where the staple is of a poor and sandy nature, mix with it soil of a tenacious character, when the whole may soon be made to suit fruit trees. If the ground by physical means be brought under the influence of the weather with a free passage for water it will quickly become more fertile, and in a proper state for sustaining and encouraging tree growth, and the improvement of the fruit both in size and quality.

As regards the proper time for lifting trees various opinions are held, but in my opinion this work should be done in the early autumn, when the weather is favourable. Commence as soon as the leaves begin to fall, and complete all planting before the bad weather comes. My reason for recommending autumn planting is because I believe the trees have a much better chance of getting their roots well established before the hot sun comes upon them, and are therefore in a better condition for the roots to supply the necessary elements for the building up and ripening of the season's growth. Plant firmly, and pay strict attention to the spreading out of the young roots, being most careful to keep them as near as possible to the surface. Make the trees secure with stakes. Plant only healthy trees, and grow varieties which have been found suitable for the locality and the position they are to occupy. With regard to their culture, I hope to have the pleasure of writing a few notes later if space is available.

—J. F. D., *Yorks.*

VEGETABLE ROOTS FOR FORCING.

MANY readers of the *Journal of Horticulture* give scant attention to the question of vegetable cultivation. This is unfortunate, as the subject is a very wide and interesting one. Respecting the details of vegetable gardening, many hazy notions exist among young craftsmen, and I propose in this short paper to deal with one point only, "vegetable roots for forcing."

It is commonly imagined that forcing merely means lifting roots in the autumn, and placing them in warm positions. There is, however, no art in the actual forcing of vegetables, as heat and moisture will accomplish all that is required. The whole secret of success is to have a supply of roots in a proper condition when required. The quality and quantity of the supply during the winter will depend largely upon the way in which the culture has been performed. No one need hope for a good crop from badly cultivated roots; on the other hand well-grown roots will always force readily, and the produce will be a credit to the grower, and give satisfaction to the consumer. Good Seakale, Asparagus, and Rhubarb in the winter months are valued more than any of the other period. A gardener who has a supply of roots from which to produce them need not worry much about the severe weather destroying his outside vegetables. When a sufficient supply of forced ones of high-class quality can be obtained, greens from the open will not be in nearly the demand they otherwise would be. This remark does not imply that one should grow nothing but forced vegetables, but that we should have at disposal a sufficient supply to bridge over any deficiency in the greens. Roots that have been forced are not of much use for planting again, so it is best to have a constant succession each year.

Sufficient Asparagus seeds should be sown annually to obtain the number of plants required. They must be left in the seed bed during the first season, and then be planted out about a couple of feet apart. By the end of the third season they will be in a good condition for forcing. Seakale, also, can be easily propagated from seed, but I think the quickest and most satisfactory way is by division of the root. If the strong roots are cut in lengths, and planted in a warm house, in a short time they will start into growth, and when the weather is favourable they can be planted out in the open by the end of March. Place in rows about 18 inches apart on rich soil, that has been well trenched and manured beforehand, and they will make splendid crowns by the following autumn.

It is, I believe, a habit in many gardens to grow Rhubarb outside till it begins to get poor, and then to dig it up for forcing. This is a great mistake, and, of course, never pays for the time and trouble. Strong healthy roots, having several prominent crowns, should be divided about the beginning of March, and planted in good soil, then splendid forcing roots will be formed by the following autumn. Rich soil, and exposure to as much sun as possible, are the chief points to be remembered in growing roots for forcing. They should never be placed, as is often done, in odd corners, but given as good a position and as much attention as is accorded to other vegetables. If they are overcrowded, and weak growths are made in the summer, good produce cannot be expected in the winter.—S. S.

FRUIT FORCING.

Cucumbers.—Plants in houses that have been in bearing since the beginning of the year may be cleared out, and the house cleansed preparatory to replanting with young plants or Melons for a late crop. This answers where there are several houses, and the plants are grown to provide fruit for marketing as regards Cucumbers; but where the old plants are fairly healthy, and fruit not supplied from other sources, such as pits or frames, they may be kept fruiting a little longer by removing some of the soil, and replacing with lumpy loam, afterwards surfacing with sweetened horse droppings. Thin-out the old growths, and encourage young in their place; shade from powerful sun, syringe in the morning and afternoon, and damp well before nightfall. Admit a little air at 75°, increasing with the advancing sun, keeping through the day at 85° to 90°, and closing early, so as to retain the latter degree, or advance to 95° or 100°. Fire heat need only be employed to maintain a night temperature of 60° to 65°, and to insure 70° to 75° by day.

Pits and Frames.—Plants in these will require attending to for ventilation from 7.30 to 8 A.M., and in the hottest part of the day a slight shade from fierce sun will be beneficial. Keep the plants watered as required, and sprinkle on fine afternoons. Avoid overcrowding the foliage, thinning well, and keeping up a succession of bearing wood.

Cherry House.—When the whole of the crop is ripe, the chief consideration will be to keep the fruit fresh and prolong the season of supply as long as possible. Shading will do so, but it is only desirable where the fruit is exposed directly to the sun, owing to limited foliage. Free ventilation must be attended to, and in hot weather a sprinkling of the surface of the border in the hottest part of the day will assist in keeping the fruit plump. The supply of water must not be neglected, for dryness is inimical to the development of the buds for the ensuing crop of fruit and health of the trees.

Peaches and Nectarines.—*Early Forced Houses.*—The early varieties, Alexander, Waterloo, Early Beatrice, and Early Louise Peaches, with Cardinal and Advance Nectarines, are nearly cleared of their fruit. The shoots on which the fruit has been borne, if not required for the extension of the tree, must be cut away to the successional growths at the base, to admit light and air freely to the foliage. Syringe forcibly to cleanse the trees of red spider, and if this pest and scale continue troublesome, promptly use an insecticide. To prevent over-maturity of the buds, ventilate to the fullest extent on all favourable occasions. Keep gross laterals stopped, but avoid checking the growth by removing large quantities of foliage at one time. Trees of the second early and mid-season varieties will now be ripening their fruit, and must not be syringed, though if the trees become infested with red spider a thorough syringing may be given when there is a prospect of a fine day. The trees must have water at the roots in sufficient quantity to keep the foliage in a healthy state.

Houses Started in January.—The fruits in the structures brought forward gently, and the varieties second early or midseason are now fast advanced towards ripening. The leaves will have been turned aside and the fruit raised, so that the apex receives most light. If the weather prove cold and wet, gentle fire heat will be necessary to secure a circulation of air constantly, as moisture deposited on the apex induces "spot," maintaining the temperature at 60° to 65° by night, and 70° to 75° by day. Cease syringing as soon as the fruit begins to ripen, and take care to have the trees free from red spider before this stage, or the pest will increase so rapidly as to prejudice future crops. Give a good watering to the border if necessary, mulching with some light material.

Succession Houses.—During stoning the trees must not be hurried, but be given time to complete the process. Allow a free extension of the laterals as an encouragement of root action, but do not crowd the principal foliage, and keep insects in check by syringing twice a day. When the fruits have stoned remove all surplus ones, and turn the others to the light, to insure their colouring well from the apex. Give thorough supplies of water through a surface mulching of manure, and supply top-dressing or liquid manure to any weakly trees. Vigorous trees, however, must not be too liberally fed, as it will only induce grossness, which must be studiously avoided. Ventilate early, and close early in the afternoon, so as to maintain a temperature of 80° to 85°, and ventilate a little afterwards for the night, the temperature being allowed to fall to between 60° and 65°.

Late Houses.—Young shoots that are to carry next year's crop must be tied-in, and allowed to extend as far as space admits, taking care to avoid overcrowding. Pinch all side shoots on extensions that are not wanted for next year's fruiting or for furnishing the trees, training a growth from the base of the present bearing shoots. In thinning the fruits, leave a few more than will be required for the crop. Keep the foliage clean by syringing twice a day in fine weather, and always early, to allow the leaves to become dry before night. Mulch the borders with short manure, and water thoroughly when necessary. Ventilate early, and increase the ventilation with the sun heat, closing early if the ripening is to be accelerated, but if wanted late keep as cool as possible.

Young Trees.—These in course of formation must be properly

disbudded, leaving the main branches or shoots about 15 or 18 inches apart, and the bearing wood at those distances along them. Train the extensions their full length, and pinch the side shoots on last year's growth to two or three leaves, so as to form spurs, and to one of subsequent growth. Laterals on current year's wood should be pinched at the first joint, and successional growths so treated as made.

THE BEE-KEEPER.

SIZE OF FRAMES.

THIS we consider of more importance than the size of the hive, for if the latter is originally large enough, it may be extended or reduced by regulating the division board. But when the frame is once made it cannot be altered without making a change throughout the hive.

It is, however, a mistake to suppose that an inch either one way or the other will make any material difference, either in the number of bees or in the weight of honey obtained from a hive. If there is a recognised size, as good as any other, in general use among bee-keepers, it is obviously as well to use it. We are therefore of the opinion that what is known as the "Standard frame" may still with advantage be used throughout the country.

FRAMES PARALLEL TO ENTRANCE.

Should frames be placed parallel to the entrance, or at right angles? The majority of the frames in our apiary are placed in the latter position, but several are parallel to the entrance. During the past winter we observed them closely to see if there were any difference in the condition of the stocks, either in the number of bees in the hives at the present time, or in the amount of stores consumed. One is similar to the other in this respect; some are strong, whereas others are weak.

We are inclined to think that during a severe winter the bees may be kept warmer if the frames are placed parallel to the entrance and the outer combs removed, the dummy being placed close up to the frames. This will allow for an open air space, and the bees will be warmer in consequence, while the brood nest may then be gradually extended in the spring. In ordinary seasons, however, one cannot detect any difference in those tried on the two systems, only what is usually observed where several stocks are kept, that some will always be stronger than others in the spring.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **8, Rose Hill Road, Wandsworth, S.W.**, and **NOT** to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Late Inquiries.—Questions which only arrived the day before making up for press cannot be answered in the present issue, in consequence of exceptional pressure.

Heating a Small Greenhouse (F. G.).—Boilers of the type illustrated in our advertising columns on the 12th inst. are extensively employed in heating such houses as you describe, set flush with one end of the house. If you write again be so good as to comply with the requirements at the head of this column as to sending name and address.

Transplanting Auriculas (H. T. H.).—We have divided and planted border Auriculas with the most satisfactory results at this season of the year when the weather is favourable, as it is now, for the operation. If dry weather follow they must be kept moist, and if in a naturally shaded position all the better. We divided and planted some ten days ago, and they do not seem to have sustained any check to growth.

A Tomato Trouble (Tomato).—As you neither know what is the matter with the plants, explain their condition nor send a sample, how do you think it possible that we can understand the case and advise thereon? See reply to "G. E. and S.," also "N. G. F.," whose cases may or may not differ from yours.

Lophospermum scandens Roots Diseased (N. G. F.).—The decay of the tissues of the fleshy roots or root stems probably arises from the heavy and moist condition of the soil. We have noticed similar cases, and usually found root-stem eelworm in association, but there is none in either the living or decayed parts of the root sent, and the threads of the fungus present do not enter the living tissues. Probably the decay has been set up by some pest, and spread by an excess of moisture. As the stem has been girdled immediately beneath the soil, the only chance of saving the plant will be by encouraging roots from the collar, above the injured part, if you consider it worth while.

The Tree Tomato (W. J. B.).—The fruit sent is a small example of *Cyphomandra betacea*, a native of Brazil, also known as *Solanum fragrans*. We figured a much larger fruit a few years ago, as grown by Rev. W. Wilks. The plant is popularly known as the Tree Tomato. Mr. Wilks' "tree" was 9 feet high, and produced many fruits, which ripened during November, December, and January, in an orchard house from which only frost was excluded. The fruit when raw has firmer flesh than the Tomato, and is slightly more acid, but when cooked is scarcely distinguishable from the ordinary Tomato. *Cyphomandra betacea* is a member of the *Solanum* family. It has been cultivated in botanical gardens for many years, but is rarely seen in private gardens. It is easily grown, and ornamental when the acute egg-shaped fruits are ripe. The leaves you sent, as large as those of fine Spinach, and equally soft, arrived quite fresh, though having been packed in soft fresh grass—the best of all material for keeping flowers and foliage fresh during transit.

Mottled Tomatoes (A. G. W.).—The Tomato is not affected by any recognised disease. The serious defect of imperfect colouring has been attributed to various causes, that of cross-fertilisation with the yellow-fruited variety being one, but we are more inclined to attribute it to soil influence as affecting the chlorophyll. We have found that the use of manures yielding nitrogen steadily, such as fish meal and native guano, with a little double sulphate of potash and magnesia, and a moderate amount of dissolved bones, dry and crumbling, give good results under such circumstances. A little sulphate of iron also tends to intensify the green and afterwards the ripening colour, not using more than a quarter of an ounce to a gallon of water, and only occasionally. There is a small black mark in the "rind," but we cannot determine this to be any form of parasitic growth, and it certainly does not extend into the adjacent tissues. We should give plenty of air and expose the plants to as much light as possible, keeping warmth in the pipes as may be necessary, so as to admit of a little air constantly. Perhaps some of our experienced correspondents will favour with their views on the serious defect indicated.

Vine Leaves and Grapes Diseased (Essex House).—The splendid leaves, deep shining green, are very slightly infested with Grape mould fungus, *Botrytis cinerea*, and the berries are affected with rust, upon which there appears a trace of mildew, *Oidium balsami*. We see no cause for alarm, as the mould has possibly been favoured by the recent wet and cold weather, necessitating keeping the house close, and the rust caused by cold air coming in contact with the berries causing a chill and contraction of the epidermis. We should dust a little sulphur on the parts affected, but not anywhere else, keeping a sharp look out, and if there are signs of the affections spreading use the flowers of sulphur all over the Vines. This we hardly think will be necessary (and it is best avoided if possible), as the little sulphur used will give off fumes, arresting the mould and mildew. It will hardly answer to use sulphur on the hot-water pipes at the present time, for the cuticle of the berries is very tender and easily rusted. If you use it there apply very lightly, and do not heat the pipes highly, but only sufficiently to give off faint fumes of sulphur. We do not know of anything you can do to prevent the reappearance of the mould and mildew, except being more careful in ventilation. In that respect we think there has been a little error at some time, which has led to the trifling mischief. The leaves and bunch are otherwise remarkably fine.

Diseased Lilium (H. T. H.).—The leaves and flower stem have been destroyed by the so-called Lily disease fungus (*Botrytis galanthina*—the conidial condition of *Sclerotinia bulborum*). It is very destructive to species of *Crocus*, *Galanthus*, *Hyacinthus*, *Lilium*, and other monocotyledonous plants, but of all useful products affects Onions the most seriously. The ways of the parasite are inscrutable. It will sometimes take whole rows of plants, at others only a patch here and there, and in some cases only destroy some parts of a plant. Possibly the tissues of the plants are weakened by some cause, and in such condition as to fall an easy prey to the fungus. We have made several experiments in this connection, and find that the differences are mainly attributable to divergences in constitutional proclivities and conformation of epidermal tissues. Only the tender growths are affected in your case, the bulb being quite sound, also the lower part of the stem; the fungus apparently having no power over the matured tissue and hardened epidermis. We advise the cutting away and burning of all the damaged parts at once, for in these appear the minute elongated black bodies or sclerotia by which the parasite passes over from year to year. After this dress the plants with best air-slaked chalk lime, dry and floury. It is easily applied to the plants by means of an old worsted stocking shaken up and down over them. This we have found of service, giving a good coat, not when wet with rain, but in the evening or morning when only very slightly damp with dew.

Vines Injured by Petroleum (G. G.).—The last year's wood has the bark damaged by the dressing, and the tissue dried to some extent, hence the sap could not rise freely, and the growths are stunted in consequence. This we consider to be mainly the cause of the present condition of the growth, combined with the bad condition of the Vines at the roots, but the petroleum has been the most active agent of the mischief. We think they will come round with careful treatment, keeping the house rather moister than usual so as to check evaporation. The lime used should be slaked, of course, preferably air slaked, and as the Vines are weak use with it an equal quantity of soot by measure, applying $\frac{1}{2}$ lb. of the mixture per square yard, and pointing into the border evenly without injuring the roots. This will improve the soil and Vines, which is very desirable.

Peach Leaves Eaten by Weevils (C. J. N.).—The small golden-bronze culprits with pitchy spots are the clay-coloured weevil (*Otiorhynchus picipes*), and the black ones the grooved or black Vine weevil (*O. sulcatus*). You have very accurately described their habits—namely, that of feeding at night, and of this advantage should be taken to capture them. They fall readily from their food plants when these are disturbed or a light is brought into their presence. Hence it is advisable to lay white cloth or paper beneath the trees in the daytime, and at night, after dark, enter the house very carefully with a bull's-eye or darkened lantern, then suddenly shake the trees, turn on the light, and capture the pests. They remain still for a short time, and are easily seen on the white surface for clearing away. We use an old tin containing a little paraffin oil for placing the beetles in as swept up. This practised for a few nights will soon reduce them and prevent much further injury being done.

Tomato Leaves Spotted (G. E. and S.).—The Tomato foliage shows spots of the fungus called *Cladosporium lycopersici*, but there are no outgrowths, these appearing to have been arrested by the cupric sulphate solution, and we do not consider the enemy can make any great headway. We should keep sufficient heat in the hot-water pipes to admit of a little air being given constantly, and during favourable weather freely. The plants cannot have too much light and air, accompanied by the requisite amount of heat, for insuring steady progressive growth. The stem and roots of the plant are quite clean and healthy, but rather weak. We do not, however, see why they should not improve and produce a good crop of fruit. It may be advisable to continue the light dressing of cupric sulphate solution, but it is not desirable to use it long after the fruit sets. Spot usually takes place at the flowering time. The main thing is to ventilate freely, taking care that the flowers do not damp, or the tender fruit scald by water hanging at the "eye." Please note the correct editorial address above, misdirection causes delay and shrivelled specimens.

Cucumber Roots Knotted (N. G. F.).—The roots have the knots or small nodosities characteristic of root eelworm (*Heterodera radicola*), and contain females embedded in the tissues. It is a pity you did not scald the soil used for top-dressing, as the plants grew so well in that they were at first planted in, and which was scalded. Perhaps, however, the pests were in the house, which you do not mention as having been treated with boiling water. Unless prompt in your application of the solution of soluble phenyle there will be little hope of saving the plants, using a wineglassful to 3 gallons of water. At this strength, 1 part soluble phenyle in 240 parts water, or 1 fluid ounce to $1\frac{1}{2}$ gallon of water, we have not found any injurious effects on the roots of Cucumber plants. For Tomatoes, 1 part soluble phenyle to 160 parts water, or 1 fluid ounce to 1 gallon of water, we found quite safe, but it would injure tender plants. One fluid ounce to 6 gallons of water will disinfect soil or prevent attack, but as a remedy is of no use whatever; indeed, prevention must be attended to, for the use of any substance after serious mischief has been done may be of little or no service.

Strawberries Diseased (G. T.).—The fruits are affected by the mould fungus (*Botrytis vulgaris*), commonly regarded as the consequence of the fruit receiving a check from currents of cold air driving full upon the tissues, and this followed by a period of damp, when the fungus pushes out growths, otherwise the fruits dry up and shrivel; but the fungus always appears under conditions favourable to its development, and is followed by small black dots or sclerotia, by which it tides over from year to year. We do not know of anything likely to arrest the spread of the fungus beyond the destruction of the affected fruits, by or before they become mouldy; to prevent against its recurrence guard as much as possible from cold winds and the other extreme of a close stagnant atmosphere, taking care not to allow moisture to be deposited on the foliage or fruit, by admitting a little air constantly and increasing it from the early part of the day. We suffered most from it with the air admitted by the ventilators driving directly on the fruit, and not at all where the air came below the shelves and the fruit not directly exposed to the powerful rays of the sun. No application will destroy the fungus, as it is wholly endophytic; besides, copper solutions cannot safely be used in such cases.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than

six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (G. S.).—The Orchid is *Lycaste aromatica*; the other flower *Cantua dependens*. (R. L.).—1, *Escallonia macrantha*; 2, *Arabis albida*; 3, *Cerasus avium flore-pleno*; 4, *C. lusitanica*; 5, *Gesnera*, species doubtful, flower injured, perhaps *G. splendens*. (W. J.).—1, *Fraxinus Ornus*, the Flowering Ash; 2, *Prunus* (*Cerasus*) *padus*. (W. P. G.).—1, *Sedum azoideum variegatum*; 2, *S. pallidum*; 3, *Cheiranthus alpinus*. (O. D. W.).—1, *Saxifraga granulata flore-pleno*; 2, *Centranthus macrosiphon*. (W. B.).—*Cerasus virginiana*. (W. J. B.).—*Cyphomandra betacea*, the Tree Tomato, see preceding.

WATER FARMING.

OF course this title must refer to the harvest of the sea, to no other branch of industry is it applicable. Indeed we do not quite agree thereto; our Editor gives us a liberal margin, but as our column is headed "Home Farm," we cannot quite stray so far as to lose ourselves in ocean depths. We try to keep on "terra firma," though at times we may sink over boot-tops in the mire. Perhaps

that is the reason why farmers are often referred to as real old "stick i'the muds;" although privately our opinion is that we move with the times, or perhaps it is that we are involuntarily carried along by the spirit of the age.

Who among Londoners is not familiar with the street cry of "Creeses, fresh Watercreeses?" The "creeses" sounded uncommonly long. That there is a great demand for this tea relish is proved by the ready sale of the quantities that find their way into not only the London markets, but into the markets of the other great cities, the centres of our thriving industries. We all require diversities of food, and he is a wise man who partakes largely of fruit and vegetable fare. That it is a natural taste is amply proved by the avidity with which children turn to anything in the fruit or vegetable line. They do not stop to discriminate between what is wholesome and what is not, and sour and unripe fruits are consumed whenever the opportunity offers. No thought of after unpleasant consequences ever act as deterrents.

We suppose that we who live among abundant garden produce are satisfied with it, and do not go far afield to find refreshing green food. For the town dwellers things are on a totally different footing. All food has to be bought and paid for in hard cash, and often at dear rates. So that when bread, meat, Potatoes, eggs, and milk are bought there is not much surplus left for other little delicacies.

The teeming population, the mass of the working classes, must have something cheap, something good of its kind, and something easily prepared. Hence the demand for the cheap salad, the Cucumber, the bunch of spring Onions, the cluster of rosy Radishes. These are only to a great extent summer delicacies, and the bunches of Watercress have to fill a large vacuum. We had till lately no idea of the extent of this kind of farming, for farming it must be called—it reaches beyond market gardening proper.

It is not often (according to our critics) that we English farmers are first in the field in any new enterprise, but this time it must be accorded to the credit of an Englishman that he was the first to make Watercress culture a study. As early as 1808 Mr. William Bradbery began to grow this form of salad as a crop at Springhead, in Kent. The name suggests the first, we might say the greatest, requisite for a successful business—"Springhead." "An abundant and perpetual stream is an absolute necessity." A stream that is not affected by summer drought, and whose flow is too strong to be frozen in winter.

Certain land, too, is more or less suited to the purpose. Sandy sub-soil entails a great outlay of capital, as the water is liable to filter away and the sides of the beds want much wharfing to make them secure. Then, again, strong clay speaks for itself—difficult of manipulation. Chalk and gravelly loam best meet the requirements of the case. But supposing the Cress grown, it does not do to be too far from a market; to be in perfection it must be eaten fresh. When we say far from a market, we mean rather within easy distance of a good train service, for from Hampshire to Liverpool is a fairly long journey.

Cress growers have several difficulties to contend with. Water rats, freshwater shrimps, water beetle, and the caddis worm, with small snails, are all enemies to the growing plant, and the water, too, produces, like the land, obnoxious weeds. Then, again, whole beds may be swept away by flood water, a catastrophe very difficult to prevent. Of course, it goes without saying that the water in which the Cress is grown must be absolutely pure; no sewage, no nastiness of any sort must approach the beds. The plant is used in an uncooked state, and therefore must be above suspicion.

The cost of making Cress beds is somewhat heavy. To prepare a bed of an acre's extent the outlay would be from £90 to £100. Then the plants would cost another £40—that is, 2 tons of plants at £20 per ton. The wages of the workmen on the Cress beds are above the average of the ordinary agricultural labourer. Cress is grown in considerable quantities still at Springhead in Kent.

Then again the waters, or rather springs, in and about Mapledurwell and Basing in Hampshire are celebrated for their growths of Cress, much of which finds its way to Liverpool—cooled in summer by being packed with ice, protected from frost in winter by coverings

of brown paper. One salesman in Covent Garden sells no Cress except that from this district. In Berkshire we find large beds near the Kennet and Avon Canal. Then, again, 30 acres of Cress are cultivated near Dorking and in Sussex. Mr. Bradbery, the grandson of the original "Springhead" pioneer, is to be found at Rickmansworth. In the basin of the Thames near Staines will be found 22 acres; on the river Gade 42; on the river Bulbarne 41; and so on in the adjacent counties of Bucks, Berks, Hampshire, and Gloucestershire.

The mode of cultivation would take too long to describe in a paper like the present, but where any person is thoroughly interested in the subject, and desirous of utilising any good springs that may exist on land in his possession, we should strongly recommend the purchase and perusal of No. 32, third series, of the "Journal of Royal Agricultural Society of England," where he will find an exhaustive paper on the subject by Mr. W. W. Glenny.

We know a rental of £50 an acre paid by a grower of Watercress and the farmer prosperous!

WORK ON THE HOME FARM.

So far May has been very deficient in sunshine, and though the rainfall has not been heavy there have been several cold drizzly days. Having had a sufficiency of rain in April, we had hoped for a dry warm May; but we have been disappointed.

Pastures grow well, and keeping at present is fairly abundant. Wheats vary much, and look on the whole fairly well, but the forward pieces are not now the best. Hoeing and weeding proceed, and as regards Wheat are nearly concluded, but much remains to be done amongst the Barley. The cold and wet have had a serious effect on the Barley and Oats of the heavier classes of land. Warmer soils have not suffered so much, but on strong or badly drained lands we have not seen Barley show a worse prospect for several years.

Second early Potatoes are coming well through. We have been covering them again for fear of frost, but shall let them come now. The haulm is coming up strong, though the seed was rather small, but it is the condition of the set rather than the size that has most effect on the growth. The soil of the Potato field must never be allowed to rest now until the plants are earthed up. Potatoes revel in freshly moved soil, besides which the constant cultivation kills every weed which might otherwise seriously compete with the intended crop.

Mangold, thanks to the moist season, have come well so far, and only want sunshine to make a most favourable start. They must be side-hoed as soon as they can be seen well. This is most important in a cold season, which checks the Mangold plants, but does not affect the hardy weeds; the latter, therefore, must be eradicated whilst they are small.

Ploughing has been the chief occupation of the horses lately. Fallows have turned up a little wet and heavy. Harrows and roller have been soon brought into requisition, or a single hot day might have baked us many a large brick.

The thrashing machine has been busy of late, for prices have been tempting, and old stacks are hardly to be found. The wind-up has been good; will the commencement after harvest be as favourable?

Butter is now very cheap, and milk being plentiful we are buying calves, as being more profitable than the churn. The vicissitudes of the farmer's life have been exemplified to us by the loss of a cow from milk fever, the first case in twenty-one years.

METEOROLOGICAL OBSERVATIONS.

15th.—Rain from 4.30 to 6 A.M., and dull and drizzly after; sunny afternoon, cloudy evening; rain at midnight.

16th.—Brilliant early, and generally sunny, but cloudy at times at midday.

17th.—Sunny early, hazy morning, with cloud at times, and dull afternoon.

18th.—Cloudless early; pleasant sunny day, though cloudy at times.

19th.—Dull, damp morning; steady heavy rain from 1.30 to 7 P.M., and showers after.

20th.—Overcast and gloomy throughout, with almost incessant rain or drizzle.

21st.—Dull and showery early; occasional gleams of sun after 10 A.M.

Rather cooler, with steady rain on 19th and 20th, but not enough to bring the total for the week up to an inch.—G. J. SYMONS.

LOST!

At the TEMPLE SHOW the ORCHIDS exhibited by M. Jules Hye, of Ghent, Belgium, disappeared from the tent on the evening of the last day of the Show.

Any person giving such information to JAMES VEITCH & SONS, Ltd., Chelsea, as will lead to their recovery, will be handsomely rewarded.

W. CLIBRAN & SON'S DESCRIPTIVE CATALOGUE

OF

Garden & Conservatory Plants.

Replete with invaluable information, is sent post free to any address on application. Buyers are invited to inspect the magnificent representative collections of every class of these plants at the OLDFIELD NURSERIES, ALTRINCHAM. To those who cannot come the fullest information as to price, sizes, &c., will be sent on request.

HERBACEOUS, ALPINE, AQUATIC, AND BOG PLANTS.

Of these alone the stock numbers several hundred thousand plants, all of the very best procurable types.

COLLECTIONS (our Selection only):—12 sorts for hot dry situations on Rockery, Walls, &c., 4/-; 12 for moist shady Rockeries, 4/-; 12 for sunny borders, 4/- and 6/-; 6 Aquatic plants for deep water, 6/-; 12 Aquatics for boggy places, 4/- and 6/-; 25 for 7/6; Asters (Michaelmas Daisies), 6 sorts for 2/6, 12 for 4/-, 25 for 7/6; Sempervivums, 12 sorts from 3/6; 50 fine showy Border perennials in 50 varieties, 15/- and 21/-; 100 ditto, in 100 varieties, 35/- and 42/- . As all these plants are supplied in pots, they may be planted out practically at any time.

HARDY CLIMBERS FOR OUTDOORS.

(Our Selection.) Clematis, 12 fine sorts from 10/6; Ivies (finest green and variegated varieties), Honeysuckles, Wistarias, self-clinging and other Virginian Creepers, Ceanothus, Menispermum, Aristolochia, 12 fine sorts in pots, 12/-.

CLIMBERS FOR GREENHOUSE AND CONSERVATORY.

Including Passion Flowers in great variety. Stephanotis (the freest blooming form), Clerodendron Balfouri, Lapageria (finest varieties), and many others at 10/- and 30/- per dozen and upwards, according to size.

STOVE AND GREENHOUSE PLANTS, FERNS, &c.

12 varieties flowering Stove Plants from 10/-; 12 varieties foliage Stove Plants from 18/-; 12 varieties Greenhouse Plants from 12/6; 12 varieties Caladiums from 12/-; 12 varieties Crotons from 24/-; 6 Epiphyllums from 7/6; 12 distinct named Gloxinias from 18/-; 12 Streptocarpus seedlings, in 3 inch pots, from 6/-; 12 double seedling Begonias, finest selected, true to colour and shade, 12/- to 30/-; 12 distinct Ferns for stove from 9/-; 12 ditto for Greenhouse from 6/-; 12 different Adiantums from 6/-; seedling Ferns for Rockeries, Table Decoration, &c., from 3/- per dozen.

DOUBLE CACTUS DAHLIAS.

SPECIAL OFFER.—12 splendid Cactus Dahlias, including the following superb Novelties of 1897:—Cycle, Ensign, Flossie, Harry Stredwick, and Mrs. Kingsley Foster, together with Beatrice, George Marlow, J. E. Frewer, Lady Penzance, Mrs. Wilson Noble, Mrs. Francis Fell, and Viscount Boyne. Post free, 12/6.

Clibrans, Altrincham & Manchester

50,000 BEGONIAS FOR BEDDING.

Very fine Singles, all Colours, Mixed, 3/- per dozen; 50, 11/-; 100, 20/-. Very fine, in eight distinct colours, 4/6 per dozen; 50, 15/-; 100, 28/-.

FINEST SINGLES, for Conservatory Decoration, in twelve distinct colours, 6/-, 9/-, and 12/- per dozen.
FINEST DOUBLES, for Conservatory Decoration, 6/-, 9/-, and 12/- per dozen.

DO YOU WANT BEST CALADIUMS, DAHLIAS, FUCHSIAS, HELIOTROPES; Fancy, Zonal, and Ivy PELARGONIUMS; Double PETUNIAS?

Send for full Descriptive Catalogue Free.

H. J. JONES, RYECROFT NURSERY, LEWISHAM.

No. 936—VOL. XXXVI., THIRD SERIES.

CARTERS' TESTED SEEDS.—In Sealed Packets. Post free. Price 2/6, 3/6, and 5/- each.

CALCEOLARIA, CARTERS' VICTORIA.—The finest in the world. Real gems of splendid habit.

CINERARIA, BRILLIANT PRIZE.—Brilliant colours, endless variety. The grandest strain ever seen.

PRIMULA, HOLBORN PRIZE.—Grand blossoms of rich colours. Single varieties, choice mixed colours; double varieties, choice mixed colours. Single, in separate colours, viz., blue, scarlet, rose, or white. Double, in separate colours, viz., crimson, lilac, rose, or white.

GLOXINIA, CARTERS' INVINCIBLE.—Magnificent blooms, brilliant colours. These cannot be surpassed.

The above in Sealed Packets, post free; price 2/6, 3/6, and 5/- each.

CARTERS', THE QUEEN'S SEEDSMEN, 237, 238, and 97, HIGH HOLBORN, LONDON.

100,000 VEITCH'S AUTUMN GIANT CAULIFLOWER PLANTS, 3/6 per 1000; Dalkeith Brussels Sprout, 2/6; Drumhead Cattle Cabbage, 2/-; Grand New Strawberry Monarch, 7/- per 100; in 60's pots, 12/- 100. 3-year Comover's Colossal Asparagus, 4/- per 100.—W. HORNE, Cliffe, Rochester.

250,000 GERANIUMS AND OTHER BEDDING PLANTS.—Paul Crampel, grand single crimson-scarlet bedder, immense truss, and very free; Henri Jacoby, crimson; Jubilee, pink; Sir Percival, white; silver variegated Flower of Spring, golden tricolor Sophia Dumaesque, double Ivy-leaf Madame Crousse, pink; and Jeanne d'Arc, white; Lobelia Brighter Blue, strong, from single pots, &c.
Catalogue and Special Prices on application.

WILLIAM POTTER, Camden Nurseries, Cranbrook, Kent

TOBACCO POWDER.—Corry's, Fowler's, or Pooley's. Introduced in 1866, and manufactured at our Bonded Stores, Shad Thames, S.E., free of duty. Tins of increased size, 1/-, 2/6, 5/- each. **TOBACCO JUICE**, 42 ozs. to the gall. In bottles, 1 pint, 1/-; 1 quart, 1/9; 1/2 gall., 2/6; 1 gall., 4/-, including bottles. —CORRY & CO., Ltd., Finsbury Street, London, and all Seedsmen and Florists.

DEFY THE BIRDS by Buying our Noted **ROTLESS TANNED NETTING**, as supplied to the Principal Gardeners in the Kingdom. Orders over 5/- value are sent Carriage Paid. 100 yds. by 1 yd., 3/-; 200 yds. by 1 yd., 6/-; 300 yds. by 1 yd., 9/-. Can supply any length and width. —UNIVERSAL SUPPLY ASSOCIATION, East Street Works, Reading. (Name Paper.)

HEATING APPARATUS. Medals 1875 and 1881. Catalogue of Boilers, Pipes, and Fittings free. W. Jones' Treatise, "Heating by Hot Water," second edition, 216 pages, 2/6; post free, 2/10.—JONES and ATTWOOD, Stourbridge.

PRIMULAS! PRIMULAS! PRIMULAS!

Williams' and other superb strains, also Primula Obconica. **CINERARIAS and BEGONIAS**, 1/6 per dozen, 10/- 100. Double White Primulas, 6d. each. All the above fit for 3 and 4-in. pots, and carriage free for cash with order.

JOHN STEVENS, The Nurseries, COVENTRY.

BEGONIAS.

B. R. DAVIS' Gold Medal Strain. The LARGEST and MOST SUPERB COLLECTION in the World, of DOUBLE and SINGLE TUBEROUS-ROOTED. See CATALOGUE and GUIDE BOOK FREE.

B. R. DAVIS, Begonia Specialist, &c., Yeovil Nurseries, SOMERSET.

Bougainvillea Cypherii. GRAND NEW PLANT.

Largest and best coloured Bougainvillea ever offered. A splendid grower and remarkably free bloomer. Awarded First-class Certificate at the Wolverhampton Floral Fete, 1896, and the Oxford Commemorative Show, 1896, and the Gold Medal at Shrewsbury Great Royal Commemorative Show, 1897, for the best new plant in the exhibition. JAMES CYPHER has great pleasure in offering this grand novelty. Plants ready end of May, price 10/6 each, **EXOTIC NURSERIES, CHELTENHAM.**

THE "SPROUGHTON" HOE.

Simpler than the Dutch Hoe and much superior. The most perfect Duplex (Push and Draw) Hoe yet made. Highly approved at Chiswick (R.H.S.), and at the Royal Gardens, Windsor. Strongly commended by Sutton & Sons, Mr. E. Molyneux, and other leading horticulturists. Copies of testimonials from Rev. A. FOSTER-MELLIAR, Sproughton, Ipswich. Price 1/10 each. Of all Ironmongers, or of **Messrs. RANSOMES, SIMS & JEFFRIES, PRINCES STREET, IPSWICH.**

Journal of Horticulture.

THURSDAY, JUNE 2, 1898.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St. London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

IS BRITAIN ADVANCING?

IT has been said that "the wealth, prosperity, and refinement of any nation may be correctly estimated by the quantity of flowers and plants employed in the adornment of its homes and gardens." If this is true—and it appears to be so to me—then, indeed, must Britain have made tremendous strides in prosperity and refinement during the last twenty-five years, for flowers seem now to enter largely into the life of almost every individual. Common species and varieties are cherished by rich and poor alike, but a pronounced feature of present times is that the latter, as well as the former, use every effort in their power to obtain and grow the best varieties of the various species they cultivate. No matter whether it be the modest Daisy or the gorgeous Orchid, as soon as any improved type is distributed there is quickly a "run" on it. To the wealthy a few pounds, or even hundreds, spent in securing something better in plant life than their neighbours is but a trifle scarcely missed, but to the toiler who spends a few shillings or pence in securing an improved form of some favourite flower, it means denying themselves of some other small luxury, or perhaps a necessity.

In country places where wages are low the wage earners can afford to spend little upon favourite flowers, still they manage by "hook or by crook" to grow good varieties of the plants they take a particular fancy to. It is done to a great extent by the exchange of seeds and cuttings, or by the kindness of some encouraging gardener at "the Hall." When judging at village shows it has often surprised me to find how up-to-date the cottagers are in the matter of varieties of plants and flowers which they exhibit. In one instance I well remember a persevering and intelligent labourer, who had long made a speciality of Carnations, set up a beautiful collection of blooms containing many new varieties, of which he had purchased rooted plants direct from a well-known specialist. The squire of the village visited the show, greatly admired the labourer's Carnations, went home discontented to his own garden, and straightway

No. 2592.—VOL. XCVIII., OLD SERIES.

sought out his gardener and wanted to know why he could not have such fine Carnations as he had that day seen at the show. The squire seemed clearly to think it was entirely his gardener's fault that they were not forthcoming. The gardener, whom I knew to be a thoroughly hard-working and good practical man, was obliged to endure in silence, because he had a young and numerous family to consider; but the following will show what chance he had of growing the best types of Carnations. He managed a garden in which the labour during the last ten years had been reduced by two-thirds, yet the whole of the pleasure grounds and kitchen garden were still expected to be kept in presentable style; but here comes the greatest poser, not one penny was allowed to be spent in the purchase of new varieties of plants, or cuttings of them. Small wonder, then, that the squire's Carnations were behind the times.

In the vicinity of large towns the rush after new varieties of popular flowers is still more marked, for those who spend so much of their time toiling in noisy workshops or smoky factories find rest, peace, fascination, in making a hobby of the cultivation of some particular flower during their few leisure hours. What could be better pastime for them, more health-giving, enjoyable, elevating? Some take up the Dahlia, and strive with all their might to come out winners at some local show; others devote their attention to Fuchsias, Pelargoniums, Roses, or Violas; and nearly all dabble in Chrysanthemum growing, even if it is only with a few early varieties in the open air. Earning, as they do, good wages, they ungrudgingly spend a considerable amount in the purchase of things that please them in the floral world. A visit to the flower markets comes as a natural part of their weekly round of shopping. Those who live in the centre of large towns, where they can not enjoy the luxury of a garden, keep their windows regularly supplied with pot plants, or their rooms adorned with a few cut flowers. Indeed, I think it may truly be said that flowers enter to an increasing extent into the lives of almost every individual in Britain, and the very poor will spend a few pence upon them as freely as they do upon life's real necessities.

Does not this all show that there is still a splendid future of prosperity for commercial horticulture, as it points to an ever-increasing demand for the common, as well as the choicer products of the gardener's art? Do not these things also show that Britain is advancing in material prosperity, in taste, in refinement, and in the real comforts of home life enjoyed by the greatest number of the inhabitants?—H. D.

WHAT WILL THE SUMMER BE?

"AN OLD GARDENER" wishes to know (page 444) whether I can tell him how many wet summers we have had during the past twenty or more years? Taking the rainfall records most readily accessible—those of my own neighbourhood—the wet and dry summers of the last forty-two years arrange themselves as follows:—

1856, dry.	1870, dry.	1884, dry.
1857, wet.	1871, average.	1885, dry.
1858, dry.	1872, wet.	1886, dry.
1859, wet.	1873, dry.	1887, dry.
1860, wet, <i>b</i> .	1874, dry.	1888, wet.
1861, average.	1875, wet, <i>a</i> .	1889, dry.
1862, dry.	1876, dry.	1890, wet.
1863, wet.	1877, average.	1891, average.
1864, dry.	1878, wet, <i>a</i> .	1892, wet, <i>a</i> .
1865, wet, <i>a</i> .	1879, wet, <i>b</i> .	1893, dry.
1866, wet, <i>a</i> .	1880, wet, <i>a</i> .	1894, average.
1867, wet.	1881, wet, <i>a</i> .	1895, wet.
1868, dry.	1882, average.	1896, dry.
1869, dry.	1883, dry.	1897, dry.

It will be seen that the wet and dry summers during the period referred to were about equally divided. Out of the seventeen wet seasons there, however, occurred only two in which the total rainfall exceeded the average quantity by 50 per cent., and but seven others when that quantity was exceeded by 25 per cent. The latter are indicated in the above table by the letter *a* and the former by the letter *b*. Moreover, had I time to go into the question more closely, it would no doubt be found that many of the summers classed in the table as wet ones, were by no means injuriously so to vegetation. For it is continuous rainy weather, rather than occasional heavy falls with sunny periods intervening, which produces that coldness of the ground and atmosphere which, after all, makes wet weather at this season so unwelcome in our gardens.

When recently investigating the question of droughts and wet periods occurring during that part of the year when most plants are in active growth, I was surprised to find how much more frequent continuous dry periods had been during the present century as compared with those marked by continued rain.

It is to be hoped that these considerations may afford some consolation to your correspondent, who appears to have such a dread of that comparatively rare experience, a really wet summer.

So far I feel on tolerably safe ground, but when he goes on to ask my opinion as to what the weather of the present summer is likely to be, I must confess myself as much at sea as any other gardener, be he young, old, or of middle age. It is quite true, as "An Old Gardener" says, that wet and dry seasons balance each other sooner or later, but they do so in such an erratic fashion that one never knows how long or how short a time they may take to settle their differences. So that I am afraid but little comfort, or the reverse, as the case may be, can be derived from the fact that dry or stormy weather is at any particular time due.

Judging from his remarks I should say that your correspondent had long been in the habit of keeping his "weather eye" open, and consequently is no doubt able in most cases to form a pretty shrewd guess as to what the weather is likely to be for several hours in advance; or perhaps he may prefer consulting the official forecasts for his own district which are published each day in the newspapers. In either case, it may not appear any great feat in the way of weather forecasting to be able to indicate with more or less certainty the atmospheric conditions likely to prevail during the next twelve or twenty-four hours. Yet, truth to tell, in the present state of our knowledge this is the utmost that we can expect in this country. Indeed, so fickle is our climate that a certain proportion of failures must be looked for even in forecasts covering such a short period of time as a single day, however carefully and skilfully they may have been prepared. I mention this in order that your readers may judge how much reliance is to be placed on those predictions they will meet with from time to time which profess to foretell with confidence the character of coming seasons.

I often doubt if those interested in horticultural pursuits would be much the wiser were we meteorologists able to let them know beforehand the general character of any season, the weather of most summers, for example, being such a strangely unequal mixture of wet and cold, and dry and warm periods. Besides which, as regards the well-being or otherwise of our gardens, so much depends upon the intensity or duration of any phenomenon. For instance, of what advantage is it to know that a certain summer will be hot if in the early part of it there should occur a killing frost, or to learn that another summer will be unusually wet if there be scarcely a drop of rain in June, the previous month having also been singularly dry? But to say nothing of the difficulty of forecasting seasons, I often find it difficult enough to describe the weather of a single month when it is past, at all events in such a way as to render the description intelligible from a gardener's point of view, so frequent have been the chances that have occurred during the course of it.—E. M., *Berkhamsted, May 30th, 1898.*

PICTORIAL GARDENING.

THE picturesque is defined by writers on æsthetics as distinct from the sublime and beautiful by the unconnectedness of its parts. But each separate or individual portion should be characterised either by beauty of form, of which the attributes are symmetry, proportion, and harmony. As the term picturesque is applied usually to landscape scenes, colour, light, and shade must play an important part in all grand pictures. The general effect of such a scene, with its light and shade, will be best judged at a distance, so that a multiplicity of minor details does not confuse the mind. A few days ago I beheld a scene that might well illustrate my remarks on the importance of light and shade.

Standing upon the highway I looked across to the west; before me was an undulating country of several miles of gently sloping green meadows and wooded knolls, in exact proportion. The background was a mountain range with many peaks, but not abrupt or rugged. The shadows of the mountains, the darkness of the trees that had not burst their buds, and the clumps of Pine and Scotch Fir, blended and contrasted with the vivid green of those trees that had assumed their new attire, and made a scene inspiring in its beauty.

Then we may lay it down as a rule that a perfect picture must be characterised by contrast and opposing masses. I have in my mind's eye a beautiful French château standing in about 100 acres of picturesque grounds. As it was situated only just across the English Channel the climate was not materially different from our own, and all the trees and shrubs I shall name are such as are hardy in the northern counties of England. Its walks might have been the origin of Hogarth's line of beauty, they were so gently serpentine and without any acute angles. Its lawns were broad (as all Nature is

broad). No shrubberies bordered its walks; nor were separated from them by narrow verges of turf, as we often see. There were shady walks through groves of deciduous trees, and ancient gnarled Yews overcanopied our paths. The shrubberies, if they may be called such, were not alternated with sombre-hued Conifers. These latter had their positions on the lawns, where their noble proportions might be distinctly seen, and were represented by *Cedrus Libani*, *C. deodara*, *Cupressus macrocarpa*, *Picea Nordmanniana*, *Cryptomeria japonica*, *Juniperus virginiana*, *Thuopsis borealis*, and *Pinus excelsa*. Amongst specimen deciduous trees were *Ailanthus glandulosa* (Tree of Heaven), Tulip Tree (*Liriodendron tulipifera*), *Acacia hispida* (Robinia), *Catalpa syringæfolia*, Scarlet-flowered Chestnut, Pendulous Birch, Weeping Ash, and Weeping Elm. The plantations of forest trees, which had been planted in clumps, were mostly on the outskirts of the grounds, and were composed of Conifers and hard woods.

The shrubs were arranged in masses. In the springtime the eye was gladdened by specimen Rhododendrons, or clumps of the same in distinct colours; spotted varieties were excluded. Masses of Ghent Azalea lent charm to the scene, with their soft and delicate colours. The grassy glades amongst the mighty trees were studded with Narcissi, Snowdrops, Primroses, and Forget-me-nots. Then we would pass a clump composed of English and Persian Lilac and Laburnums. All were given sufficient room for full development. Another clump would be double-flowering Cherry, Siberian Crab, and Almond trees. There were *Forsythia suspensa* (unpruned) and masses of *Pyrus japonica*, each alone. *Magnolia conspicua* was a mountain of snow. The Costorphine Plane and Norway Maple lent a glow of golden light to the scene. *Ribes sanguinea*, Guelder Roses, Mock Orange (*Philadelphus coronarius*), and double-flowering Thorns were here also in groups.

Summer and autumn flowering, or autumn tinted leaves would oppose the groups of spring flowers, and so a picture of colour and diversity of light and shade filled seven months of the year. Amongst the groups of summer and autumn flowers were *Spiræa aræfolia*, *Lindleyana*, *confusa*, *Douglasi*, and *Thunbergi*; *Deutzia crenata* fl.-pl., *Weigela* in variety, *Cornus sanguinea*, and its gold and silver variegated forms; *Hydrangea hortensis*, *H. paniculata*; *Buddleia globosa*; *Berberis stenophylla*, *B. dulcis*, *B. vulgaris*; *Snowy Mespilus*; *Ceanothus azureus*, and *C. Gloire de Versailles*; *Fuchsia Riccartoni*, *F. corallina*; *Escallonia macrantha*, *E. Phillipiana*, and *Arbutus unedo*, beautiful both in flower and fruit.

During the summer the groups of *Acer Negundo variegata*, *Prunus Pissardi*, and Golden Elder, the three mixed in numerous groups, lent a touch of colour and warmth. The golden hued Conifers were in unimixed masses, and included the following varieties, which appear to be the only ones out of numbers of so-called variegated Conifers that are worthy of a place in a collection from the distinctness and brightness of their hues—*Retinospora plumosa aurea*, *R. obtusa aurea*, *Cupressus Lawsoniana lutea*, and *Thuia occidentalis aurea*.

Autumn was resplendent in the glow of colour with Siberian Crab and *Cratægus Crus-galli* in fruit, and leaf tints of green, gold, crimson, and russet. *Cratægus pyracantha* and *C. pyracantha Lelandi*, with their coral berries, and the Mountain Ash, lent its scarlet to the show. The Scarlet Oak (*Quercus coccinea*), Scarlet Maple (*Acer rubrum*), and *Acer colchicum rubrum*, *Rhus*, and *Dimorphanthus mandshuricus*, all added their radiance to the glorious autumn days. As the grounds of this fair place were undulating, and in some parts the slope was sharp and steep, the banks from high to low ground were planted with masses of *Berberis aquifolia*, *B. vulgaris atro-purpurea* (rich crimson, in leafage), *Vincas major* and *minor*, and the golden and silver variegated foliage varieties. *Hypericum calycinum*, *Erica carnea* and *E. herbacea* were beautiful with their pink bells, as were Gorse and Broom; *Juniperus sabina* and *J. communis* also clothed these banks.

A winding stream had planted on its banks clumps of Bamboos, Guelder Roses, red, yellow, and black-twigged Willows; the latter enlivened the banks of the stream in winter with their warmth of colour. All trees and shrubs were unrestrained in growth. There was some pruning, but no contorting with the shears; all groups and masses were irregular in outline, and no exact measured distances had been observed. This was a place without iron or wood palings or tree guards, and there were no so-called rustic arbours or alcoves—it was given up to beauty of Nature alone.

There was no regular flower garden, but around the outskirts of the lawns were large circular beds in which scarlet "Geraniums," flowering Cannas, *Lobelia cardinalis*, *Zinnia elegans*, *Salvia splendens*, *S. coccinea*, *Coleus Verschaffelti*, *Iresines*, and *Alternanthera*, with numerous fine-foliaged sub-tropical plants were placed. *Chamærops Fortunei*, *Chamærops excelsa*, and *Musas* gave brightness and character to the whole. Within this domain was a rockwork. Not such as we often see, a pile of stones placed as if there had been a violent upheaval from the centre of the earth, but a piece of natural rockwork like the sides of an alpine pass, bared in places to show the stone. The crevices that held sufficient soil were planted with *Ajuga reptans*,

Alyssum saxatile, *Antennaria maritima*, *A. tomentosa*, *Arabis alba*, *A. alba variegata*, *Aubrietia græca*, *Campanula pumila*, *C. pumila alba*, *Gentiana acaulis*, blue Hepaticas, *Iberis saxatilis*, *Saxifraga* in variety, *Sedums*, *Vincas*, and *Daphne cneorum*. This rock garden was the face of a natural declivity with a northern aspect, and bounded one side of the sweeping gravel approach to the château.

It may not, perhaps, be possible in lesser places to plant the great variety of trees and shrubs here mentioned, and to plant them in separate groups or in groups composed of three varieties, yet it is possible to give more distinctness to shrubberies, and thereby add to the picturesqueness of a place by planting in groups of threes, fives, or greater numbers than by the all too prevalent dotting and alternating system.

This article would be incomplete without a few words on colour. The hybridist, in his eagerness for new varieties, has sent into commerce in all departments of the garden plants whose flowers are spotty and indistinct, and we should, if we wish to be effective, steer clear of such confusing colours as these. Beauty of colour defined by æsthetical writers is characterised by purity, brightness and softness found only in hues, tints, and shades. The first are those primary colours, red, yellow, and azure, and their secondaries produced in combination, and the tertiaries resulting from the combination of the secondaries. All other colours are either tints or shades. The tints are produced by the admixture of white, and the shades by the addition of black. To attempt analogous harmonies in such a circumscribed space as the petals of a flower is almost absurd; and even in essaying harmonies of contrast with tints of the same colour one should be intense and the other soft, and then the intensity of the one will be heightened, and the softness of the other mellowed.—F. STREET.

LESSONS OF THE SEASONS.

SPRINGTIME, with its trying alternations of clouds and sunshine, heat and cold, scathing nor'easters, soft balmy breezes, rain and drought, brings to the gardener anxiety and encouragement—lessons by the way, which make the sum of that euphonious term, "dear bought experience." And as the years roll by, filling the brief span of time which marks our existence on this earth, we gather wisdom; we are bound to do so if we read, mark, and record the lessons brought to us season by season, applying them subsequently to our practice in furtherance of that striving for success, that steady improvement, which is the end and aim of every earnest intelligent tiller of the soil.

Surely it may be claimed, as a result of experience so gained, that last autumn, when the summer crops were gathered in, we had every bit of bare soil thrown up roughly, in view of as complete a destruction of the larvæ of insect pests as might be, and of that fine deep seed bed in spring, which the action of rain, frost, wind during winter upon soil so exposed renders a certainty. Aye! sure enough have we long ago come to regard autumn as the ending and beginning of the gardening year. The very fact of reaping brings to mind the certainty that seed time will come round again right speedily, for the seasons are so interwoven, have such a mutual influence upon each other, that one tells upon another for good or evil—not altogether, but certainly in no inconsiderable degree, according to how we prepare for it. Let full recognition be accorded to the importance of this work of preparation, to the acquisition of sufficient knowledge to enable us to do all we can, and to grasp the reason why of the matter.

On the evening of the 21st of last September I went to an allotment field to hold a demonstration—an informal open-air lecture in which attention is called to object lessons in the gardens in view of imparting instruction. On these occasions one first of all goes round the gardens, for inspection and a chat with the men as one after another they join in the stroll, and then comes the address. The theme of conversation this time was the frost of a week ago which had cut off the Runner Beans, blackened the Potato haulm, and so brought the season of growth to an abrupt and premature conclusion.

The discussion of this catastrophe brought out the fact that these gardens were so liable to early frost in autumn and late frost in spring, that the crops were always sown late and gathered early. The reason of this was self-evident; the land was heavy and wet; it was equally obvious that the men did not understand how serious an evil this was, or that it was really the cause of the frost. The matter was made plain to them that evening; they were told how vapour was constantly given off by waterlogged soil; how on the night of that fatal frost all the crops were enveloped by a dense mist from this source; how the frost which would cut them off under such conditions would do no harm to similar crops on drier soil. Attention was also called to unmistakable natural indications of the sodden condition of the soil, for there before us were patches of Coltsfoot (*Tussilago Farfara*), and Horse-tail (*Equisetum*), best known in the Midlands as Joint Grass.

Having thus explained the cause of the evil, the remedy was

made equally clear. The surface of the land had an unbroken slope from one side of the allotments to the other; close at hand was the cinder-tip of some blast furnaces, literally a mountain of slag, and there was no provision of water for the gardens. The advice given was to get the water out of the heavy land by drains laid 15 feet apart, make holes of puddled clay at intervals along the lower sides of the allotment as reservoirs for the water, then work into the soil a heavy dressing of fine slag to open it up and impart thorough mechanical division, and there would be perfect water filtration combined with air circulation, warm dry soil, a cessation of abnormally early and late frost, and a supply of water for the gardens in summer.

A large order for the allotment holders certainly, but a perfect remedy, in the application of which I have reason to believe assistance will be given by a kindly generous landlord, rendering this lesson of the seasons fruitful of good, and this particular effort of technical education by the County Council of Derbyshire a memorable one.

—EDWARD LUCKHURST.

THE HISTORY OF THE SOILS OF THE BRITISH ISLES.

(Continued from page 370.)

HAVING thus referred to the most marked and important agencies that have operated in the disruption and dispersal of the ingredients of the crust of the earth, we may next seek for the results, and examine and remark on the various formations either producing or having already contributed to the friable matters that we recognise as soil. We shall deal first with the rock formations and the soils derived immediately from them, which may be styled primitive or natural soil; when these have been noticed *seriatim*, we shall proceed with the various amalgamated soils, such as alluvium and loam.

In its first aspect, we have in granite or crystalline rocks of apparently uncompromising hardness; but the most compact and obdurate rocks, though yielding slowly to atmospheric agencies, decay at last, and their fragments all assist in giving the rocky skeleton of the earth its garment of soil. The accumulation of soil derived directly from the waste of granite rocks (which contain chiefly quartz, feldspar, and mica), though not invariably characterised by fertility, have under certain circumstances an appreciable value. Enriched, it forms the base of a most valuable soil, it is always porous and receptive, and its slow decomposition gives it great permanence as a soil. The products of cultivation of Jersey, in soil derived from crystalline rocks, prove its great value; and, under less favourable circumstances of climate, the granitic soils of Aberdeenshire produce good results both in corn and cattle.

Trap rock, though excessively hard, has, like other compact mineral substances, yielded to the operation of atmospheric and other agencies wherever large surfaces have been exposed. The results of its decomposition are found in a soil of considerable fertility, and the intermixture of its particles with other matters greatly enhances its value.

In their primitive form the soils of the Silurian system are not greatly remarkable for fertility. It is in the collections of matter the various strata contribute to the accumulations peculiar to the system that the best results in soil are found.

In the Devonian system we have the old red sandstone, a formation that affords extensive tracts of rich land in Herefordshire, Shropshire, Moray, and other districts. It affords a soil eminently capable of improvement, and suitable for a great variety of crops. Its horticultural value is considerable, and some of the best results in Vine culture have been obtained from this soil.

The soils produced by the several divisions of the great carboniferous formation are of a very marked and distinct character. The millstone grit, in its extensive development in Northumberland, Yorkshire, and Derbyshire, affords a soil from the disintegrated stone of greater interest and utility to the horticulturist than to the farmer. Distinctly siliceous in character until enriched by decayed vegetable matter it is of the least possible value, and its poverty and generally elevated position have caused large areas to be left in an uncultivated condition. Where thus left we have an illustration of the way in which rocky surfaces are operated upon by organic and inorganic agencies, with the result of producing in course of time the peaty soil so valuable in horticultural practice.

The rocky surface is first covered by the lower forms of vegetable life, mosses and lichens. The former of these plants send their roots into every crevice. Their peculiar structure enables them to absorb and retain water; this assists the moss to dissolve small portions of the rock it has already partially softened. The plant thus creates its own food. The annual growth and decay of mosses, their power of arresting particles borne by winds, and their action on the stone beneath, together contribute to the production of a soil. The process becomes more rapid when *Fungus*, *Carex*, *Heath*, *Vaccinious*, and *Grass* successively appear, with the result of the continued accession of

organic matter, and the constant softening of rocky surface acted upon by the plants. As the soil deepens a still higher class of plant or plants of a more nutritious character appear; and when these are followed by the introduction of cattle the land is still further enriched, and at length becomes of some value to the forester and farmer. In the depressions of surfaces and hollows of this formation, where water rests, great accumulations of boggy soil are found. This is greatly due to the growth and decay of water-loving Mosses, such as sphagnum; but the unctuous black bog soil thus formed is not suitable for plants, although by desiccation and exposure it serves certain purposes.

The varied character of the soil of the coal measures is naturally due to the particular rocks or clays which have a surface development. When the laminated clays of the system are uppermost, the result of atmospheric action, wood, and cultivation, produce a thin soil better adapted for grazing land than gardening; and the aspect of the rolling or sometimes boldly undulating face of the country, beneath which lie so much mineral wealth, is often cheerless; where great rifts or profound valleys are found in the formation, exposing the strata derived from the waste of granitic, Silurian, and old red sandstone formations, the commingled matters washed out by streams and deposited by their action in neighbouring valleys, form loams of the greatest possible value to the gardener; but these will be described more fully when we treat of those deposits.

The mountain limestone, which, by its extensive development, is one of the important as well as the most marked in character of any divisions of the system to which it belongs, possesses in itself that great element of fertility, lime, enriched by the presence of the fossils which contribute to its production. It is found crowning the hills of Yorkshire, Derbyshire, and Westmoreland, and its hard and durable texture better resists the wasting action of the element. The soils resting immediately upon it are necessarily calcareous, and somewhat shallow, and support a marked and characteristic flora—Pines, Firs, and deciduous forest trees generally thrive, and, with preparation, good fruit tree soils are produced. The formation of soil from such rock is largely mechanical: the roots of the trees, now covering extensive tracts, penetrate every crevice, and at length break up and dislocate the rocky crust. Frost and snow, rain and drought, are factors of varying importance, according to exposure, and all these agencies are working with the same result, and tend to the increase of soil on the surface of the rock.

The notice of the soils of the carboniferous system would be incomplete without reference to the sandstones, which form part of the coal measures, and which, in some instances, are presented on the surface, and, like the other parts of the formation, give, by the decay or disintegration, a soil of less marked character than either grit or limestone, but intermediate in value between them. Sandstones, grits, magnesian limestone, and gypseous marls characterise the Permian system, and give some very distinct primitive soils. The rocky divisions of the formation each afford soils by the decomposition of their exposed surfaces, and these naturally partake of the mineral character of the stone from which they are derived. The soils from the pure sandstone are poor, shallow, supporting naturally a meagre vegetation. The grits are equally poor, but more strongly siliceous. The limestone has produced a soil of a somewhat superior character, atmospheric action having removed the lime, and neutralised the obnoxious products of the stone exposed to its influence. The marls are usually tenacious, and the sulphate of lime derived from the gypseous deposits with which the marl is associated gives a distinct character, and certain elements of fertility under tillage.

The trias comprising the keuper, the bunter, and the new red sandstone present in two of its important divisions some general characteristics in texture, colour, and mineral constituents; but in the bunter, as exposed in Sherwood Forest and Cannock Chase, there is a marked difference. In the first named there is found both in the compact marls accumulations, and in the sandstone a certain amount of sulphate of lime. The exposure and consequent disintegration of the saliferous and gypseous shales have given their own peculiar character to the resulting soils. Occupying generally a good mean elevation, and often assuming a boldly undulating character, the marls and sandstones of the trias afford a valuable series of soils, on the former of which orchard fruits may be cultivated with marked success. The lighter soils of the sandstones are of less value, but useful for special gardening purposes. The bunter conglomerate is not invariably found, as its name implies; in a fixed and consolidated condition; its superficial exposure exhibits a pure sandy soil, intermixed with small water-worn pebbles; its purity is proved by the excellence of the water spring filtered through it; a soil that has no marked chemical properties is nevertheless of great value to horticulturists; it is a base for whatever additions are needed. In its pristine state it is suitable for Heaths, and with additions of vegetable soil *Camellias* thrive in a compost of which it forms the greater part.

—PERCY T. INGRAM.

(To be continued.)

LÆLIO-CATTLEYA WELLSIANA LANGLEYENSIS.

THIS is the third bigeneric hybrid that Messrs. J. Veitch & Sons have introduced from a cross between *Lælia purpurata* and *Cattleya Trianae*. The first was *L.-C. Wellsiana*, the second *L.-C. Wellsiana albida*, while the third, which is depicted in the illustration (fig. 86), has the above distinctive title. It is certainly the finest of the trio, as was observed in the Chelsea nursery recently, the flowers being not only larger but more substantial and much richer in colour, throughout all the parts. The broad, handsome petals are rich rose flushed with purple, the sepals being a delicate blush. The splendid lip is velvety purplish maroon, deepening towards the throat, which is yellow with rose at the base. When the plant was exhibited at the Drill Hall, on April 26th, the Orchid Committee of the Royal Horticultural Society accorded to it a first-class certificate.

ONCIDIUM LOXENSE.

ALL the *Oncidium*s with long scandent scapes of flowers are beautiful, but not many are more so than this rare species, which is now in flower. The plants, when strong, produce spikes a couple of yards or more in length and many-flowered, the individual flowers about 3 inches across. The sepals and petals are brown, with yellowish markings showing through as it were, but the golden orange tint seen on the incurved lip is really beautiful. Its culture is similar to that recommended for *O. macranthum*, and it comes from Loxa in Ecuador.

DENDROBIUM CUCULLATUM.

This is now in flower, and although it is distinct from *D. Pierardi* it is questionable if it deserves specific rank. The flowers are very freely produced, and highly attractive if the plants can be suspended in front of a wall of greenery of some kind, or Maidenhair Fern. They have an almost semi-transparent character, and are beautiful in the mass. It is an easily cultivated though not particularly strong-growing plant, and thrives under the conditions advised for the long bulbed deciduous *Dendrobium*s generally. Its pendant habit especially fits it for basket culture.

ONCIDIUM LURIDUM.

If we except *O. Lanceanum*, the ebulbous species of *Oncidium* do not seem to be at all popular, yet many of them are very interesting and beautiful. The above, for instance, is one of the finest of the West Indian species, yet it is seldom seen under cultivation. It is interesting as one of the Orchids known to Linnæus, and the great botanist placed it, in common with all the exotic Orchids he knew, into the genus *Epidendrum*. The flower spikes spring from the base of the leaves, the latter being upwards of a foot in length, slightly spotted in most varieties.

The scapes often grow 4 feet or 5 feet long, and carry a large number of blossoms, these in the type being reddish brown, with a few yellow bar-like markings. It is, however, a very variable kind, so cannot be determined by colour alone. It may be grown in

medium sized pots nearly filled with drainage, three parts of sphagnum moss being used to one of peat fibre, and plenty of rough opening material. Though there are no pseudo-bulbs, the large fleshy or leathery leaves store a lot of nutriment; and though not requiring to be actually dried off in winter, much less moisture is then needed than in the growing season.—H. R. R.

A BRITON IN BELGIUM.

(Continued from page 387.)

IT is not necessary to get half so far out of Antwerp as Ghent, to see good gardening. Nor is it necessary to get more than two

FIG 86.—LÆLIO CATTLEYA WELLSIANA LANGLEYENSIS.

or three miles out of the suburbs to find at least one beautiful and remarkable garden. When a man starts to learn a bicycle at eighty years of age, depend upon it there is something in him vastly out of the common. Well, there is such a man, and he is the same whose name has become famous among lovers of hardy plants as the builder of one of the most wonderful rockeries in Europe. Those who are fortunate enough to see the garden and enjoy the hospitality of M. and Mme. Everaerts, of Vieux-Dieu, near Antwerp, will long remember the experience. The rock garden is a monument of loving industry. With its many ramifications, its banks and recesses, its peaks and valleys, its slopes and summits, a calculation as to area is completely baffled; but many and many a square rod of rooting space, many and many a ton of stones, are represented in the great work. It is the labour of a lifetime, the hobby of a busy man of the world, whose brief hours of leisure have known one great desire. And it is still going on. At eighty-two the veteran builder rises with the dawn, draws from his piles of stones and works on. He talks, with a perennial faith and

composure, of the extensions that are to be made. He speaks of the pleasant past, of the hopeful future.

On these garden Alps flowers of nearly every genus bloom. As far as may be, the conditions of existence of every species in its mountain home are copied. There is more than the plain features of display and adornment; there is an intimate study of the requirements of the plants for their own sake. It is as though the grower did not strive to snatch from the plant its beauty, but to set on it the crown of its own health and contentment. If this be so—and it was the impression which I for one gathered strongly—it suggests a love for Nature which must inevitably sweeten life's thorny pathway to a degree which selfish culture can never attain. The beautiful mass of *Eritrichium nanum*, with its azure lake of sunny blossom, the soft cushion of silvery Saxifrage on the grey promontory, are not simply to be spoken of as gay lumps of carbon pressed into the service of mankind, but as objects of solicitude and care, of affection, I might almost say of reverence. There is a new and appealing beauty in this view of gardening. It is the unwritten poetry of flower culture.

To mention half the beautiful plants on the Antwerp Alps would be to draw up something like a catalogue, and as I have a rooted dislike to note-taking, which awakens reminiscences of feverish work in stuffy tents in past years, when yard-long reports were being prepared for waiting presses, I resort to it only as a last extremity. Far sweeter is it to drink in the pleasure of a garden like this in such draughts as Nature gives, and through her own media. The interposition of paper and pencil would be appropriate only in the hands of an artist, who could pourtray natural beauty as only those wonderful Dutch and Flemish painters have been able to do. It may be said that through note-taking comes information. True, but not inspiration. And it is through inspiration rather than through abstract learning that there comes capacity for putting into force, either in gardens or on canvas, those mysterious impulses of genius which have made the little kingdoms of the Low Countries such vast powers in civilised life.

Thus it is that I am no more going to make an attempt to describe the materials with which M. and Madame Everaerts have built up their unique and beautiful garden than to indicate the separate colours employed by Rubens and Rembrandt, Hobbema and Van Dyck, Van der Neer and Wouwerman, or other great artists of the Dutch and Flemish school. Antwerp throws open its beautiful art galleries free to the world, and I have very strangely misread the disposition of the hospitable pair mentioned above if they would decline to permit any traveller animated by a pure love of horticulture to see the work which they have done. The visitor does not see merely one of the most astonishing and remarkable rock gardens of Europe, but groves of beautiful trees and shrubs, naturalised wherever possible, including small forests of Rhododendrons, snowy mounds of Andromedas, and huge old clumps of Magnolias, studded with bloom. He finds colonies of plants, colonies of trees, colonies of birds, and even colonies of fish, the last giving a chronometer-like touch to Nature by the accuracy with which they assemble at the pond edges when the hour has arrived to expect the master and mistress with the early morning meal.

There will be seen, too, beautiful borders of hardy herbaceous plants, extending in the aggregate to half a mile long or more, and full of choice flowers; an extensive Rose garden, comprising all classes of plants and long lists of varieties; a large collection of hardy fruits, carefully grown and pruned; houses of Strawberries; houses of Roses; houses of this plant and that plant and the other—in fact, every item of a great private horticultural establishment, where everything that is thought worth growing is thought worthy of being grown well. When the head gardener appeared on the scene he proved to be what might have been anticipated—an intelligent, active, earnest man. In connection with him I had a pleasant surprise. The Belgian spoke English much better than the Briton did French, and he—the Belgian—had learned our tongue under the encouragement of his employers for the express purpose of reading our gardening papers. If the editorial blue pencil has become at all impatient over these jottings, I am sure it will learn composure at the news that the practical articles in the Journal are closely scanned every week, and the hints given put freely into practice.

Having the blue pencil still before my eyes, in spite of a triumphant sense of having momentarily disarmed it, I refrain from making this pleasant little tribute to British horticultural journalism the text for a homily on gardeners' education. Warily, too, must I tread in a comparison of the readiness with which the Belgian gardener brought out his note-book at the mention of any new name, and the caution, almost amounting to suspicion, with which a new thing is often greeted here in Great Britain, lest I draw sarcastic charges from indignant horticulturists that I am younger than I ought to be.

Humbly acknowledging this damaging trait of mine, I still venture to mention a forcing Strawberry which struck me as good; it was being grown by hundreds, I might also say by thousands, and appeared to be remarkably free. While the Briton was making a mental note of the name (it is called Vilmorin's) the Belgian was putting into the ever-ready note-book the name of Royal Sovereign, which will speedily have to undergo a test of superiority with the French sort.

Speaking of Strawberries reminds me of an allusion by Madame Everaerts to a variety grown years ago in her ancestral home near Aix-la-Chapelle, which had many distinctive qualities. It was a fruit of good size, very dark in colour, in fact almost black, and having so powerful an aroma that a few fruits of it would perfume a whole basket of another sort. Its other most notable feature was a negative one—great sparsity of fruiting. All qualities, good and bad, are mentioned, because they are characteristic of the sort, and may help to identify it. If any Strawberry specialist recognises the variety let him send the name along for publication. It was much prized by the lady of the house, but unhappily, owing to its being a poor fruiter, it fell under the ban of a former gardener, who promptly threw it away. This particular gardener is spoken of with a certain mingling of awe, wonder, and admiration. Only equal to his sublime knowledge of every branch of gardening was the sublime calmness with which he denied the most rudimentary knowledge of the art to his employers. Do you imitate my own thoughtless act, and inquire his nationality? Then the truth must out, though thrones may totter and dynasties collapse. He was a Briton, too!

After this blow to the national pride it would gratify me to pass on to something comforting. Well, I found it—for myself—but can only transmit it in the form of a hint. Hundreds of acres of land around Brussels are devoted to the culture of a vegetable which is rarely seen here except in large country gardens. I allude to Witloef. That it is grown by us to a limited extent I happen to have the best means of knowing—namely, concurrence in the distribution of seed. But the almost complete absence of the vegetable from our markets, and the rarity with which it is included in menu cards, tell their own story. Now, Witloef étuvé, that is, Witloef boiled, then browned in a saucepan and served with sauce, is an exceedingly tender and wholesome vegetable. It is as melting as Seakale, but the flavour, otherwise somewhat similar, has a bitter reaction reminiscent of Turnip tops, so that you lose your Seakale comparison all in a hurry. Those whose palate is robust enough to appreciate an occasional dish of Turnip tops would soon become very fond of Witloef. Nothing could be much simpler than the way in which the Belgians secure a spring supply. They grow the roots in deep and well-pulverised soil, lift them in autumn, trim off the tops, replant, and cover thickly with straw. The price this April was about 4d. per lb.—W. PEA.

(To be concluded.)

LATE GARDEN TULIPS.

It is no disparagement to the English florists' Tulips to say that they are better suited for cultivation in a bed, properly protected and shaded, than for undergoing the vicissitudes of growing among border flowers. For this purpose there is nothing finer than the Tulips with self or almost self-coloured blooms. A very beautiful gathering of nine different flowers, sent me by Mr. Wm. B. Hartland, is before me now. Some of these I grow, but as there are others I have not had, it may be more convenient to take them as they are. Very brilliant is *T. fulgens lutea*, with long, rather narrow, petals of the brightest yellow. Fine, too, is *elegans lutea*, bright yellow, flushed with orange red, of pretty form and large in size. A pretty form of *T. Billietiana*, a variable species, has rather paler yellow, shorter, and rounder-petalled flowers, strongly marked with carmine. *T. ixioides* is a charming yellow flower, but with black spots at the base of the interior, and with black anthers. Two exquisitely delicately coloured flowers are *T. Leghorn Bonnet* and *T. flava*. I presume the name Leghorn Bonnet is taken from the pale straw colour of the flower. *T. flava* is of much the same shade, but whiter towards the base and round the margins of the flowers. Bridesmaid is a Tulip with dark crimson ground, resembling the old double Pæony, but feathered broadly with white. It is very large. The Moor is a deep brownish red. One bearing the awkward name of *T. Gesneriana* major *rosea cœrulea* is deep rose red, with blue at the base. I have had this for years under the same name, with the exception of "rosea." *Gesnera aurantia maculata* is magnificent in its colouring, and one despairs of trying to describe the combination of rose, orange, and yellow, with the intermediate tints of shading it possesses. Such flowers as these are more brilliant than the Darwin Tulips, and are more elegant among other flowers by reason of their less formally shaped blooms.—S. ARNOTT.

[We wonder if our closely observant correspondent has been impressed by the fragrance of the brilliant *T. macrospila*. It was obtained from Messrs. Barr, and is a general favourite.]

HARMFUL AND HARMLESS GARDEN MOTHS—21.

YEARS ago, when the Crystal Palace was not built, and people on the South of London visited the old Beulah Spa as a health resort, the vicinity of Norwood abounded with those black wooden fences which are the delight of moths, also of entomologists. For these fences were often then the temporary abiding place of choice species, both of moths and beetles, which had bred in the gardens thereabout, or in the woods, which were still extensive fifty years ago. A worthy friend of mine made many a search along these palings, seeking the silvery arches, or *Aplecta tinctoria*, and was rewarded with a few. It is a moth not common in Surrey nor in other counties, but the caterpillar lived on some of the Birches which adorned the Norwood hills. It is one singular in appearance, the body being marked with depressed rings, its general colour brown, upon which are numerous tiny spots of black and white; it hibernates, becoming adult during May.

The moth is certainly one of the prettiest of our Noctuas, though the colours are not conspicuous, the surface being glossy grey, with bands or lines of silvery brown. June and July are its months of emergence. Not an injurious species, but its relative, the grey arches, a more abundant moth (*A. nebulosa*), may, in caterpillar form, commit some damage during the spring, for this insect, living at first upon low plants, afterwards ascends trees, eating the buds and young leaves of several ornamental species. It is brown above and pale beneath, dotted with black, and having behind the head a horny plate. In May it enters the earth, the moth emerging in about a month, when it is fond of resting by day on walls or fences. On examining one we shall find it whitish grey, or some darker shade, exhibiting those marblings and wavy lines which are characteristic of the group.

At the end of May, or early in June, the dark brocade moth (*Hadena adusta*) deposits eggs upon various garden plants. It is a dull-coloured insect, the bar and patches being not much darker than the general brown of the wings. The caterpillar is yellowish green, sometimes tinged with pink, faintly striped; on the sides are black and white spots. After feeding on low plants during the summer it often resorts to Sallow in September, and devours the flower buds of the next season, then returns again to the herbage near, usually entering the earth in October to become a chrysalis. Still better known is the caterpillar of the pot-herb moth, so-called by gardeners, but which entomologists have named the brown line, bright eye, or *H. oleracea*. Of recent years we have had fewer reports about the destructiveness of this insect. It is perhaps not identified at times amongst its many brethren that pursue the method, of hiding by day just under the soil, doing mischief to roots, then at dusk emerging to attack stems and leaves. This has been taken on Cabbages, Broccoli, Lettuce, and no doubt will occasionally help to clear off Docks or kindred weeds. The moth is brown, showing a line of white like the letter W, and a blotch deeper in hue than the ground colour. Usually the caterpillar is pale green, striped with brown and yellow; between the stripes are rows of black dots. It feeds during the autumn months.

At that season, too, occurs the caterpillar of the broom moth (*H. Pisi*), which I have had brought to me now and then as a curiosity, from one or other of the London suburbs; it is also found in many other places. This is a beautifully marked caterpillar, the stripes being green and yellow; between these are narrow lines of white and black. Though the English name associates it with Broom, I have mostly taken it off the common Brake Fern. The Latin name is appropriate, for the moth sometimes visits gardens, laying eggs upon Peas and Beans; but so conspicuous a caterpillar can be easily removed. The moth is generally on the wing before midsummer; it is reddish-brown, faintly marked.

We may consider the nutmeg (*Hadena Chenopodii*) to be rather a useful moth. It is one of the many species that come in July to flowers after sunset; a grey-brown insect, obscurely mottled, having three pale lines crossing the wings. It is not, however, by any means so common as the caterpillar, which either suffers from ichneumon foci, or else often falls a prey to birds. Possibly they are attracted to it by its conspicuous colours, for it is a pretty caterpillar, though of moderate size. The green body has netted markings of black, its sides show white spots, and four pink stripes run from head to tail. In August it is mostly observable, feeding upon the *Chenopodiums* or Goosefoots, which are frequently abundant upon waste ground and about neglected gardens. Should there appear a specimen that we recognise of a companion moth, called the dog's-tooth (*H. suasa*), we give it a welcome, for the caterpillar is a devourer of the Knotgrass, feeding by night, and resting during the daytime in the sphinx attitude, the front segments raised and curved, while it holds on tightly by the hinder ones. Like some other of the *Noctua* tribe, the colour is variable, green or brown, but it always shows a yellow stripe along each side, edged with black. July and August are its months of feeding; the moth emerges early next summer, and is

named from some wedge-shaped markings of dark brown, which point towards the base of the wing.

One of the first Noctuas to appear in spring is the early grey (*Xylocampa lithorhiza*), which comes out defying the gales and showers of March. When fresh from the chrysalis this moth has a beautiful rosy tint, which soon vanishes. Its plumage is rather downy, appropriate to a species exposed to our spring, greyish, with tracings of dark brown and some black spots. The females resort to Honeysuckle in gardens or woods. Young caterpillars emerge from the eggs during June, and, as they grow, become noticeable on the slender stems of their food-plant, sitting with the head stretched out, while the legs hold tightly, but they drop if alarmed, forming a ring. Towards the tail its body is narrower, in colour greyish-brown, and a pale stripe extends along the back. Early, too, is the much larger and conspicuous sword-grass moth (*Calocampa exoleta*) which, however, makes its appearance first in October, haunting Ivy bloom, or late garden flowers at night, then before long hibernates. The wings are pale grey, having a few dark lines; the discoidal spots are very distinct, and contain light centres. In colour the caterpillar surpasses the moth. It is velvety green; on each side are two stripes; one of these is yellow, and has above it a row of black and white spots; below this is another stripe of brilliant scarlet, bordered with white, the legs reddish-green. Commonly it feeds from May to July on the creeping Field Thistle, also sometimes on the Scabious species and the Bladder Campion.

We come next to the shark moths; not as caterpillars do they exhibit quite the ravenous nature of the fish, but are still somewhat voracious eaters of leaves, especially from their often occurring in companies. The shark (*Cucullia umbratica*) type of the group, is frequently observed resting on walls, or on those grey park palings, which it exactly resembles in colour, about the middle of June. Like the other sharks, it has narrow wings, which have a few black lines on the general grey, and the thorax is crested. Some seasons the caterpillar does notable injury to the garden Lettuce, secreting itself amongst the lower leaves that lie on the ground or are curled over. Occasionally it lives upon Sow Thistles, which is some set-off to the mischief it does. The body of the caterpillar is dark brown, or nearly black, crossed by pale shagreened markings, and two segments have several orange spots. It feeds in July and August. Some years ago a gardener brought me China Asters which had been attacked by the caterpillar of the Starwort (*C. Asteris*). It is found also in woods feeding upon that plant and the Golden Rod. This has a long slim body which is green striped with blue and yellow. It goes underground during September, and the moth emerges in June. Another of these sharks is called the mullein moth (*C. Verbasci*). It has rich umber-brown wings, a band of light brown, and two pale crescents; it usually appears during May. The caterpillars are stout and showy, feeding in parties, the general colour whitish green, on which are yellow and black spots; they are partial to the hoary and other Mulleins.—ENTOMOLOGIST.

THE CULTIVATION OF WALLFLOWERS.

BEDS of Wallflowers, either mixed varieties or separate colours, are so showy and sweet-scented at this season that few persons would care to dispense with them altogether from their collection of spring flowers. Dwarf, bushy, well-grown Wallflowers are excellent plants for furnishing beds and borders in winter, and for this reason, apart from their wealth of fragrant flowers, they command considerable attention. Good, bushy examples, however, will not be forthcoming in autumn if seed is not sown at once. Choose a piece of moist, fertile soil, that has been dug and manured some time previously. An open border on a north or east aspect is, perhaps, the best, but they will succeed on a hot south or west aspect unless the soil should be shallow and poor.

In preparing to sow the seeds break down lumpy particles and remove large stones, bringing the surface to a fine tilth. Make perfectly level with the aid of a rake. If the soil is very dry it is not desirable to sow the seed before giving it a copious moistening through a fine-rosed can. Moisture is very essential to cause germination. Scatter the seed, not necessarily scantily, but evenly, so that the seedlings do not come up in crowded patches. Seed may be sown in drills, but the broadcasting method is superior. A quantity of fine soil ought to be at hand for the purpose of spreading over the seed and hiding it from sight. Dust dry soil is as good as moist for covering the seed when the soil was previously watered. It will prevent the moisture escaping.

Under favourable conditions the seeds will quickly germinate. To assist the seedlings in advancing vigorously they must be watered occasionally in the course of very dry periods. They will not require daily waterings. In July preparation must be made to prick out the seedlings in order that they may strengthen and become the bushy plants wanted. Dig over a piece of ground in an open position. Providing it is not very poor and shallow no addition in the form of manure or leaf soil is required, any excess of organic matter being liable to produce a strong succulent growth.

Transplant the young plants in rows 6 or 8 inches apart. I find it a ready method to take out a trench with a spade, laying the plants

on the face of the trench about 4 inches asunder. Cover in a portion of the soil over the roots, making it firm, and apply a soaking of water, then fill up with the remaining soil. Treat each row in the same way. Little, if any, water will be required afterwards. Of course transplanting may be effected with a trowel if the soil is sufficiently moist, as new rootlets will soon form therein. The only culture required is to keep down weeds, stirring also the soil several times until the plants have advanced so that this will be impossible.

The result of transplanting is to give a fresh impetus to the production of fibrous roots, and as each plant is favoured with room to develop, side shoots extend, forming in due course the compact bushy plants sought for. Such move easily in autumn for planting in permanent situations in beds, borders, vases, and window boxes.

For general purposes it is best to sow a packet of seed containing a mixture of all the best single varieties. The market variety is the blood red or dark brown. Sutton's Dwarf Bedding varieties are remarkable for their dwarf compact habit, growing about 6 inches high, colours brown and yellow. For an early display of Wallflowers through the autumn and winter, Sutton's Earliest of All is the best variety I have tried. The colour is yellow.

Double Wallflowers are more ornamental than useful, and if these are cultivated seed of a good reliable strain of double German ought to be procured. Plants from such strains are invariably dwarf and compact in habit, and produce fine spikes about a foot in length well furnished with flowers of a Balsam-like character, sweet-scented, and of various shades of colour. Give the plants moderately rich soil in an open position, affording slight support to the spikes as they come into bloom.—E. D. S.

WEATHER IN LONDON.—Holiday keepers can congratulate themselves on having had comparatively fine weather for Whitsuntide. Though it was dull and threatening at times, no more than light showers fell in the metropolis between Thursday and Whit-Monday evening, when rain fell steadily, while at frequent intervals the sun shone pleasantly. On Tuesday it was wet almost the whole of the day, but Wednesday opened brilliantly, but heavy rain fell later.

WEATHER IN THE NORTH.—Rain, which fell sparingly on Tuesday morning, was beginning to be much wished for after a week of rather ungenial weather. Several of the nights were decidedly frosty, and for several days a strong drought, with bright sunshine and cold high winds, prevailed. Rumours of considerable damage to bush and other fruits are heard.—B. D., *S. Perthshire*.

ADONIS VERNALIS.—It is doubtful if there is a more interesting or showy hardy plant in blossom on the rockery or in the herbaceous border in April, yet how seldom do we see the plant at all in an ordinary garden. One would imagine, from its apparent scarcity, that it was new, whereas it was introduced as far back as the year 1629. Although it will succeed in the herbaceous border, its proper place appears to be in a fissure between two pieces of rock, where it can obtain a deep rooting space, deriving the necessary amount of moisture without stagnation. Propagation is effected by division of the roots, but it is not advisable to interfere more with the plant than is absolutely necessary, as it does not increase in bulk rapidly, although it will flower freely annually. When in bud the back of each petal exhibits a dark-coloured patch, which is not discernible when the flowers are fully expanded. It is the lustre of colour that renders this so charming a plant for the hardy garden.—E. M.

RADISHES.—There was at the Temple Show a remarkable display of Radishes, but in so many cases were the roots quite past eating value, and too large. There is an almost interminable variety now in commerce, early and late, olive, round, and tapering, red, white, carmine, purple, and white-tipped, short-tipped, and long-tipped, all very nice in their season if pulled when quite young, but if not, then absolutely worthless. These roots when shown in this way should be set up only when just fit to eat, and then alone. If past the crisp stage they should be left at home. It is because pulled so large that we rarely get in the market at this time of the year really good edible Radishes. Then how few varieties is it needful to grow. The first Early Olive, white and red, the pretty white-tipped French Breakfast, the good Turnip-rooted red and white, and finally, if desired, Wood's Frame or the Long Red. These varieties satisfy most ordinary requirements in private gardens.—OBSERVER.

SERIOUS LOSS OF ORCHIDS FROM THE TEMPLE SHOW.—We are informed that at the Temple Show Mons. Jules Hye of Ghent lost the very valuable Orchids he exhibited, and no trace can be ascertained of their whereabouts. They were seen by him in the tent soon after 9 P.M. on the Friday, but they had disappeared by ten o'clock, and he is naturally in great distress. We understand that a reward will be paid for their recovery.

TEMPLE SHOW AWARDS.—In the list of medals and cups that were awarded to exhibitors at this show, we omitted to state that Messrs. R. Wallace & Co., Colchester, received a silver-gilt Banksian medal for their beautiful collection of hardy flowers.

ASPARAGUS AT THE TEMPLE SHOW.—As a reader of your Journal for a number of years, I must ask you to correct an error of your reference to Asparagus at the Temple Gardens. The large bundle you refer to as Castle Ashby produce was exhibited by me, and I was awarded a silver medal for the same. If you refer to your Journal of 1894, June 13th, you will find you described my exhibits of Asparagus as splendid, and such as were seldom seen.—WALTER GODFREY, *Colchester*. [We have more than once or twice admired the splendid produce of Mr. Godfrey, and thank him for his note. Our only desire is to be correct.]

BROCCOLIS AT THE TEMPLE.—When anyone is engaged in the work of reporting such a show as was that at the Temple last week, he has in the rush little time to reflect or talk; but during the second day a leisurely look round enables the reporter to see and note many things that the first day in the hurry could not be dwelt upon. Thus it was, that looking over the collections of vegetables I overheard the remark, "The Broccolis all have different names, yet they are all just alike." That remark induced me to look over these Broccolis rather more carefully, and I found nine diverse names, yet there were hardly more than two varieties, Late Queen and Model, shown. How much easier to thus manufacture names than real varieties. The Council of the R.H.S. is prompt to exclude from hardy cut flowers any duplicate bunches; it is much more tolerant with vegetables, some things coming in collections over and over again. Let us have these collections of vegetables and fruit also by all means, but let everything be shown under their true names, and then only of the finest quality.—OBSERVER.

ROYAL GARDENERS' ORPHAN FUND.—A meeting was held on May 26th, when the following special receipts were reported—viz., his Grace the Duke of Rutland per Mr. Divers £5; Sir R. Hargreaves Rogers, £5 5s.; the Hugh Low Cricket Club, sale of bats and balls, £3 7s.; Mr. Witty, Nunhead Cemetery, box in show houses, £1 15s. 6d.; Francis Robinson, £1; proceeds sale of gold ring received from an "Anonymous Lover of Flowers," £1 6s.

BECKENHAM HORTICULTURAL SOCIETY.—We have received the schedule of the summer show of this active society, which is advertised to take place on July 27th. It is a good and comprehensive schedule, with classes for almost everything in season, and fifty-nine of these classes "open to all." There are others for amateurs, cottagers, and children, the whole numbering 114; a diversified display may therefore be expected in the Recreation Grounds on the date named.

THE NATIONAL CO-OPERATIVE FLOWER SHOW.—The new schedule of this annual show has just been issued. The prices are again increased, and amount to over £350 in cash, besides medals, framed certificates, and other awards. The Agricultural and Horticultural Association contributes over £200 to the prize list, and the Crystal Palace Company £150. The show is fixed to be held on Friday, the 19th, and Saturday, the 20th of August, at the Crystal Palace, concurrently with the Great National Co-operative Festival. Mr. G. Waugh again acts as Hon. Director of the Show, and Mr. E. O. Greening as Hon. Secretary. Copies of the schedule may be obtained free of charge on application to the Hon. Secretary, at 3, Agar Street, Charing Cross, W.C.

LAXTON'S LEADER STRAWBERRY FOR FORCING.—Royal Sovereign is known as a general favourite for forcing, and well deserves its reputation. Laxton's Leader, a newer Strawberry, has been forced here under exactly the same treatment, and side by side with Royal Sovereign has come in ten days earlier, producing larger fruits and of better flavour, many of the fruits exceeding an ounce each in weight. President follows, but has not the clean, healthy habit of either of the above varieties; it is, moreover, subject to mildew, and the fruits are smaller, yet its flavour is superior to them both.—JOHN WALKER, *Fairfield Gardens, Cobham*.

— **BROCCOLI.**—Sutton's Large Protecting is one of the best of Broccoli for spring use. A glance at the plants growing in May would lead one to think they were so many Cabbages, as the heads first form in that way. A close inspection, however, reveals charming white heads carefully protected by several leaf coverings, which render the heads of unusual purity in colour.—E. MOLYNEUX.

— **MARROWFAT PEAS.**—At the Temple Show the exhibit of Messrs Sutton's new Marrowfat Peas caused quite a sensation. As noted in our list of awards last week it received the highest honours in the vegetable division from the judges, and subsequently two large baskets of the Peas (Sutton's Early Giant) were by command of the Prince of Wales sent to Marlborough House in time to be served at the Derby dinner given by his Royal Highness.

— **PRESENTATION TO MR. J. GRAY.**—Mr. Gray having resigned his position of head gardener to Sir George Meyrick, Bart., Bodorgan, the under gardeners took the occasion to present to him before leaving a case of handsome carvers, bearing the following inscription:—"Presented to Mr. J. Gray as a token of respect by the assistant gardeners of Bodorgan, upon his leaving the charge of Bodorgan Gardens, Anglesea, North Wales, May, 1898." Those who have visited these gardens will know how much they have been improved whilst under the charge of Mr. Gray, whose departure from the district was much regretted by all.

— **COLEUSES FROM SEED.**—A splendid selection of handsomely coloured and marked Coleuses may be raised from seed. Reliable strains are offered by all the leading seed firms. To successfully raise plants, however, and grow them on to a useful size, heat is required. For germination bottom heat is desirable, so that there may be a quick and rapid growth from the first. Sow the seed in a light sandy mixture of loam, peat, and leaf soil, and when the seedlings can be well handled place them in small pots. Give plenty of heat and moisture at this stage. Shift as required into larger pots, 5-inch size being suitable for plants for ordinary decoration. In summer grow close to the glass in a sunny greenhouse, or one of intermediate temperature.—E.

— **THOSE TERRIBLE WOMEN.**—I have no doubt very many of your readers, in common with myself, were greatly amused over the East Cowes gardeners' manifesto and the horticultural ladies. Talk about not meeting trouble half way, our Island friends seem anxious to rush all the way they can to meet the trouble, of which after all there is no earthly danger. It is so obvious that no woman who is not prepared to assume man's attire, his responsibilities and his labours, can ever hope to displace him. I gravely doubt whether any woman, however clever she may be, contemplates anything of the kind. She may hope to find some employment of an horticultural nature suitable to her physical capacities; and she has the most perfect right to do so. I cannot understand the action of men who enjoy freedom denying it to the opposite sex. Is it not about time more sensible views as to woman's position in the world were held?—A. D.

— **WHITE COMMEMORATIVE FLOWERS.**—Many admirers of the late Mr. Gladstone have expressed strong desire that the anniversary of his death should be commemorated by the wearing of some white flower, Roses, Lilies of the Valley, and various others having been specially mentioned. As this is a proposal, if adopted, likely to have great interest for market growers of flowers, because nothing wild and common will suit the case, I have ventured to make a list of various white flowers, forced and otherwise, that can be had in considerable abundance on the 19th of May. White Roses have been specially indicated, but it is suggested that not enough could be produced to satisfy popular demands. That may be so, but capacities to meet such demands seem to be illimitable. No doubt the wiser proposal would be to require white flowers of any kind, and that would insure the provision of abundance. Specially reliable are white Roses, double Narcissi, Carnations, Lily of the Valley, Gardenias, Gladioli The Bride, Anthericum liliastrium, Orchids, Stephanotis, Bouvardia Humboldti, double Begonias, Eucharis amazonica, Lilium Harrisii, Pansies, Violas, Marguerites, Saxifraga granulata flore-pleno, white Scilla campanulata, Spiræa double white, Gloxinias, Irises, Pelargoniums, Stocks, and many others. This list shows that white flowers may be had in plenty, if desired, to suit the pockets of even the poorest. Whenever floral emblems are utilised it is rather important they should be of a cultivated order, because that means trade for the grower and an encouragement of home industry. It is a double satisfaction to lovers of buttonhole flowers if they can feel that whilst administering to their own pleasure they are encouraging labour, and thus making their gratification doubly reproductive.—A. D.

— **PYRUS FLORIBUNDA ATRO-SANGUINEA.**—The typical *P. floribunda* is very popular among gardeners, being one of the best decorative species. The variety under notice has also attracted a considerable amount of attention during the last few years on account of its richly coloured flowers. In habit it does not differ materially from the type, making a dense bush 8 to 10 feet high, and producing its flowers with great freedom. The usefulness of the plant is apparent, as it grows and flowers well in almost any position if given a little good soil to begin with. For shrubberies, groups in parks, or other places, it is equally suitable, while small plants potted in autumn and forced gently, make a pleasing addition to the occupants of greenhouse or conservatory in February and March.—G. K.

— **SULPHATE OF IRON FOR VINE DISEASES.**—According to French investigations the use is recommended of sulphate of iron as a winter treatment for the prevention of black rot, oïdium, mildew, and anthracnose of the Grape. The method of application recommended is to bathe or sprinkle the Vines with a 10 per cent. solution of sulphate of iron, and place the powdered sulphate about the Vines at the rate of 400 to 800 lbs. per acre, the quantity depending on the porosity of the soil. The use of sulphate of iron solution, as mentioned above, has been made in America for some years past for the prevention of anthracnose. The best method of making the application is with a brush, after the pruning has been done.

— **THE PERENNIAL PEAS.**—Occasionally in old-fashioned gardens one meets with masses of the perennial Sweet Pea, *Lathyrus latifolius*, and charming flowers they are in the early summer. Year after year, with scarcely any attention, they make their appearance, and their bright flowers are extremely useful for decoration. Once there, always there, may be said of the perennial Pea, and I know of a wild spot "where once a garden smiled," and there, with unfailing regularity, the *Lathyrus latifolius* produces nosegays for the school children to pick. In addition to the variety mentioned with its bunches of red flowers, there are *L. latifolius splendens*, a fine dark variety; *L. latifolius albus*, which produces large white flowers extremely useful for cutting, and *L. grandiflorus*, with large blossoms of a crimson scarlet tint.—H.

— **BEDDING PELARGONIUM WEST BRIGHTON GEM.**—The time has not yet come when Zonal Pelargoniums can be dispensed with for bedding purposes. The above variety recommends itself by its dwarf habit and the brightness of its scarlet trusses. The majority of these plants have the unfortunate habit, particularly in damp seasons, of making a superabundance of foliage at the expense of flowers. West Brighton Gem is far superior to many of its compeers in this respect. The wood is short-jointed and hard, even in wet seasons, and the output of flower continual, while in average summers the beds are a mass of brilliancy till late in the autumn if the old trusses are continually kept picked off. As with other varieties, the best results are obtained when the ground is not made too rich with manure, either natural or chemical.—G.

— **JAPANESE MAPLES.**—It was to me strange, that having such singularly beautiful dwarf trees and bushes of these lovely Acers at the Temple Show, only about one exhibitor made any really decorative use of them. When looking at the flat, though richly coloured, Caladiums in a few large groups, I could but think how much more beautiful would these leaf plants have appeared could they have been set under the overhanging leafage of the cut-leaved Maples. Oh, for the touch of a vanished hand, such as was that of the late John Wills, who would, out of the superb materials that some of our nurserymen possess, have created marvellous groups of exquisite charm and beauty. Why numerous collections of Maples should have been crowded into tents, rather than have been fully and effectively displayed outdoors, especially with a carpet of moss, in the same way Messrs. Fisher, Son, & Sibray did their fine groups, was inexplicable. This method of showing these plants in tents misleads the public somewhat, as they get to regard them as tender, needing greenhouse culture, whereas they do finely outdoors in the summer; some, indeed, well all through the winter. Then I marvel no one yet seems to have utilised them for bedding purposes in the summer. How charming would a dozen or so of nice heads look on a carpet of white, blue, or pink. I noted as very pleasing for this purpose *Acer palmatum dissectum* (green), and *A. purpureum* (red). These have lovely cut leafage. *A. reticulatum*, foliage pallid green veined dark green, and free growing, is a beautiful variety. *Acer rufifolium* has rich red leafage. Less red, but very pleasing, and dwarfer, is *Acer lineatifolium atro-purpureum*. *A. polymorphum purpureum* is good also. Charming, too, is *A. septemlobum elegans*, *A. sanguineum*, *A. japonicum aureum*, and *A. niskikigasane*—a horrid name, but a beautiful variety all the same.—A. D.

COB-NUTS AND FILBERTS.

(Concluded from page 422.)

PRUNING.

It is not a difficult matter to prune a bush that has been properly trained on the lines described, but to commence pruning one of the overgrown shapeless specimens such as are frequently met with is another matter, and therefore, perhaps wisely, they are generally left alone. Again, Nuts are frequently left unpruned because the grower is not quite sure which is the fruiting wood, and for this reason the pruning may be left till the end of March or early in April, when both catkins and female flowers will be open. Nuts produce fruit on the upper part of young shoots on spurs, and on the twiggy growth that is emitted from the main stems. The leaders of the main branches may be shortened on the orthodox method to about two-thirds their length each season, until they have reached the required height, after which they may be treated as spurs. Strong side shoots can be shortened to two or three buds, and will form spurs, and, while avoiding congestion, short twiggy growth that never fails to produce fruit blossoms should be encouraged, and in pruning care must always be taken to leave sufficient catkins or flowers for fertilisation. Kentish growers always prune close to the main stems, so that after the process the bushes have quite a skeleton appearance.

SOIL AND CULTIVATION.

Some of the best Nut plantations in Kent are on hillsides and sloping banks where the soil is not necessarily of a particularly fertile character, but friable and naturally well drained. Nuts appear to have a partiality for a rooting medium of somewhat brashy nature, and in many places where a shallow soil rests on the famous Kentish ragstone Cob-Nuts are abundantly produced. Low situations should be avoided, as bloom is liable to be destroyed by late spring frosts, and land holding water should be drained before planting, otherwise growth will be too rank. Though Nuts are grown in some districts on a chalk subsoil, it is generally where "rag" prevails that the most plantations are found. Ground should be broken up and worked prior to planting, and well established specimens give a quicker and better return than do recently rooted layers or suckers taken from the old bushes.

Nuts are grown either as an entire crop or with standard and bush fruit. Under the former system the bushes are disposed from 10 to 12 feet apart where the soil is good and the situation favourable. When planted between standard Apples and Plums the Nut bushes must necessarily be kept low, the advantage of this system being that the former act as a protection, and on this account it is favoured. Black Currants and other bush fruit are also grown between Nuts, and in this case the latter are given a wider distance between the rows. By this method the ground may be utilised to advantage while the Nuts are becoming established and come into bearing. Surface cultivation of the soil in plantations during the summer is good, and in the autumn after the leaves have fallen the bushes are examined, all sucker growth removed, and an application of farmyard manure forked in among them, together with the fallen leaves. Rag waste is used in some Kentish plantations at the rate of about 1 ton to the acre; also quick-acting fertilisers are applied as surface dressings in the spring.

VARIETIES.

Cobs and Filberts are to the uninitiated one and the same thing, but the difference is that the Cob Nut is round, and not covered by the husk, while the Filbert is oblong and entirely covered. Probably the best all-round Nut in cultivation is Lambert Filbert. This variety is largely grown in Kent under the name of Kentish Cob, and is sold as such. The mistake in nomenclature has doubtless arisen through custom, as the Nut is a Filbert with a fine oblong kernel, and the tree is hardy and a prolific bearer. The purple Filbert makes a handsome ornamental tree with its dark purple foliage, and as such it is grown in pleasure grounds, for which it is better adapted than in plantations. There are also red and white Filberts, so called from the colour of the kernels. Among Cob Nuts Cosford is a vigorous grower, producing a large white kernel. Merveille de Bollwyller is a true Cob with short husk and large shell. Pearson's Prolific makes a dwarf bush, and is suitable for planting under standard trees. The habit is sturdy and compact, the shells being well filled with sweet kernels.

GENERALITIES.

In order to keep Nuts in good condition as long as possible they must in the first place be left on the bushes till thoroughly ripe. After picking they should be laid thinly on dry shelves where the air can circulate freely through them. If not wanted for immediate use the husks, when dead and dry, may be removed, the Nuts placed in jars and fastened down perfectly air-tight. Nuts so treated and stood in a dry cool place will keep for a considerable time. Squirrels, rats,

and mice are all partial to Nuts, the former in woodland districts, where they abound, doing so much damage among the bushes that stringent measures have to be taken. Amongst the insect pests the Nut weevil, *Balaninus* (*Curculio*) *nucum*, is the most deadly. In May the female deposits an egg in the young fruit, and the larva when hatched feeds on the kernel and then eats its way out, falls to the ground, and passes into a chrysalis state. By way of remedy the bushes may be shaken in May, spreading sheets beneath to catch the beetles. If treated the same way in August all affected Nuts will fall, and they should at once be deposited in the fire. Soot and lime worked into the soil in the spring are disagreeable to the pests and beneficial to the Nuts.—A WORKER.

NOTES ON MELONS IN FRAMES.

(Concluded from page 403.)

STOPPING, TRAINING, AND SETTING.

WHEN the plant puts forth one rough leaf and then another, rub off the knob-like joint without injuring either of the leaves, to induce the production of two strong shoots in place of the one. Let these make six leaves, then again rub off the leads, and there will be a number of shoots, which only need a little training to let the sun get at them all as evenly as possible, to cover the bed with regularity. The stopping will give rise to several lateral branches with staminate and pistillate blossoms showing all over the plant. That is just what is wanted to get a good set—namely, several fruit blossoms fit for fertilising at one time. The shoots that reach first to within 6 inches of the sides of the frame must have their ends pinched off, and when the fruit is set and swelling the superfluous growths are thinned out or stopped, so that they do not interfere with light to the principal leaves. Even before setting any refractory growths are either stopped or cut away to secure an equality for all of space, and thus give every shoot a chance.

When the flowers appear a little ventilation keeps the air in motion, and moisture does not condense on the flowers to the ruin of the pollen and pistils. A slight warmth from lining the sides of the frame with grass mowings then does good, as it allows air to be given, especially in dull weather. If only a fruit blossom appears at first on a plant, nip it off, but two being expanded in one day, fertilise about noon, repeating this daily till enough fruit has set, which is easily seen by their commencing to swell. Whenever fertilising a flower pinch out the point of the lateral a joint beyond. From four to six are sufficient on a plant, for it is overcropping and overfeeding that take quality out of Melons. Steady supplies of nourishment, extracted slowly from a hard soil, make Melons as hard as cricket balls, and as luscious as honey inside. Set each fruit on a slate so that water will run off it. Clear away all flowers and fruits that are not required.

WATERING.

Up to the flowering period only give sufficient water to keep the plants in steady growth, and this is the most difficult point in the whole matter. If too much be given, the plants will produce so many leaves that the laterals carrying fruit will be smothered; if too little, the plants may become stunted, and red spider seize on them. The soil must neither be dust dry nor sodden, but just between the two, no water being given whilst it is in that state. But when it is getting dry, and the foliage is becoming a little limp under powerful sun, afford a fair supply. I water mine in fine weather twice a week, and in dull once, or not even that. Slight flagging is not always a sign of water being required, for excessive evaporation will cause it whilst the soil is quite moist, and a slight shading is better under such circumstances than a deluge of water. When flowering and setting withhold water, and while the fruit is swelling neither drown the plants nor let them perish through drought. On fine afternoons a light sprinkling, always keeping water from the stems of the plants, helps wonderfully, and prevents red spider. Before the process of ripening begins the soil should have a good store of moisture, in order that none will be required from that time until the fruit is cut, during which interval the surface of the soil should be kept perfectly dry.

RIPENING.

When the fruit has netted and the rind is hard it seems to concentrate its energies on the perfecting of the seeds, growing very little unless kept in a warm close atmosphere and lavishly fed at the roots. This is the period to get quality. It will not come at the finish unless stamina be there to support the effort; therefore do not over-feed, but keep steady, and when the fruit begins to change colour—a keen eye knowing long before the aroma pervades the air—add a lining (it is really astonishing what virtue there is in grass mowings), and also a little air day and night. If the fruit has been grown in partial shade do not expose it suddenly to the fierce rays of the sun, but let it ripen where grown, as the bine will pour its stores.

of matter into it, and it will ripen, and tell a pleasant tale on the palate. Cut directly the fruit is fairly ripe, and is giving out a good smell. I think cutting too soon an error, and letting the sun shine fiercely on the fruit for a day or two still worse, as it ripens too fast on that side and too little on the other. It is better to shade a little than to bake them, and use when evenly ripened all over. Then is the time to eat a Melon, and always before dead ripe, yet with the flesh melting to the rind, and that not much thicker than a sixpence. —EXPERIMENTALIST.

FRUIT NOTES—HATFIELD.

ROYAL GEORGE PEACH.—This fine old Peach seems to be a favourite at Hatfield, for there are two trees of it there, each covering the entire side of the roof of a 50-feet span house, but one is rather deeper than the other. One carries 400 fruits, these spread over so great an area, being comparatively thin, to secure a very fine sample; and the other has 350 fruits. Mr. Norman does not believe in overcropping, as it is in the end too exhausting. Each tree is on a tall clean stem that is a capital stock, as, in both cases, these stems have so admirably swollen with the trees.

FIG. 87.—RUBUS DELICIOSUS.

RUBUS DELICIOSUS.

IN several places about the gardens at Kew large masses of this may be seen in flower. It is, from a flowering point of view, by far the most ornamental of the hardy species, producing in great profusion its pure white blossoms. The flowers (fig. 87) are about the size of those of the "Dog Rose," though one form has flowers which are considerably larger.

In habit it makes a strong upright bush, from 4 to 6 feet or more in height, with leaves resembling those of *Neillia opulifolia* to a certain degree. The wood resembles that plant even more than the leaves, it being difficult to distinguish the two when not in leaf. The fruit is red when ripe, but not palatable. This *Rubus* grows well in sandy loam, to which a liberal quantity of manure has been added. It will be found advisable after flowering to cut out some of the old wood, to allow of strong young shoots being made. It can be rooted from cuttings, but not readily. The best methods of propagating are seeds or layers. It is a native of the Rocky Mountains.—D.

On the obverse side of each house there are smaller and dwarfer trees; but these two Royal Georges, with their 50 feet length each, are remarkable ones.

PEARS.—There are lengths of Pear wall at Hatfield that it would be difficult to find excelled anywhere. The walls are all stuccoed and wired, hence there is no nailing, a matter of the greatest importance so far as labour is concerned. It is there possible to look along great lengths of high wall and see from end to end every foot of wire fully furnished and the trees as clean and in luxuriant health as well can be. In the stable yard and on some ancient buildings adjoining are fine trained trees worked on the Whitethorn stock that are doing well, and showing that this stock has not, in these cases at least, that straggling character so often attributed to it. Out in the open, bush trees in great numbers and of considerable size are set most freely with fruits, there being promise of a heavy crop. Certainly trees should now find great benefit from the month's heavy rains, and it may in consequence be well to allow free wood growth for a little while that the strong, inevitable sap flow, may be utilised to thoroughly swell the fruits.

APPLE BUSH CORDONS.—This as a descriptive term seems to be a contradiction, but at Hatfield, where there are hundreds of great bush

trees, every one seems to be composed of a series of spurred cordons, for each branch stands out from any other, separate, and with ample room, reaching to lengths of from 8 to 12 feet, so placed that if swayed by the wind, they do not in any case beat one against another. When I saw the Apple trees recently nearly all were in full bloom, for flowering is rather later on the north than on the south side of London. Should the set be as good as the blossom warrants, then the crop next autumn would be worth seeing. Trees of this nature, planted 20 feet apart, and so trained, should in bulk yield a wonderful crop. Mr. Salter, at Woodhatch Reigate, prunes his bush trees in just the same way, and he obtains fine, results and noble fruits.—A VISITOR.

NEW ROSES.

I HAVE read with much interest "D., Deal's," contribution on this special subject to page 426. While on the whole coinciding with his observations, I think he somewhat underestimates the value of Clara Watson, which was in my own garden during last summer the grandest of the Hybrid Teas. I am, aware, however, that it does not succeed so admirably in other regions; and perhaps the weather is too hot for it occasionally in the south of England. I am glad to find that Clio is appreciated by your veteran contributor. Waltham Standard I have in my garden for the first time this year; but I had the privilege of seeing it last summer at its native place in magnificent bloom.

Mrs. W. J. Grant is very bright and beautiful in its earlier stages of floral development; I do not, however, find it quite so impressive when fully expanded; the promise it gives in bud form, however great, is by no means realised. In this respect I think it is much inferior to La France or Lady Mary Fitzwilliam, the richly fragrant and nobly endowed varieties from which it was derived.—DAVID R. WILLIAMSON.

NEW ROSES OF 1897-8.

NOW that the spring lists have arrived, it may be of some service to amateur growers to know those which have been found really good by other rosarians than the raisers. Unfortunately we have a formidable list each year, and few of them are of sterling merit. Those I name, and briefly describe below, have either flowered well in this country, or have been seen by more than one reliable authority. They may, therefore, be considered worthy of trial by those with only small Rose gardens. I do not propose touching upon any but those varieties sent out in 1897, or during the present spring.

KILLARNEY.—This made a favourable impression on me on more than one occasion. It is a constant bloomer and of free habit. The flowers are large, the buds pointed, of great length, and the colour a unique combination of flesh shaded with white and pale pink. It is a good Rose, and will be a general favourite when known.

DAISY.—Though only a moderate grower, this variety flowers freely, and the blooms are large, full, and of perfect form. Colour a rosy pink suffused with soft silvery pink. It has the merit of being exceedingly fragrant.

COUNTESS OF CALEDON.—The N.R.S. "card of commendation" was accorded to this at Derby in 1895. I have grown it, and find it a good habited variety, and quite perpetual. The colour is rich carmine rose, and the flowers are splendidly formed.

ROBERT DUNCAN.—A grand Rose, with large flowers composed of stout petals of a bright rosy lake colour. It is one of the best flowers of this shade.

BERYL.—This is likely to be useful because of its free habit and continuous blooming. The long pointed buds are sure to be popular as coat flowers, being of a distinct deep golden yellow, and very highly scented.

ARDS ROVER.—In this variety we have a deep crimson and maroon climber. It should prove useful considering that most of our climbers are light in colour.

MURIEL GRAHAME.—Of this I need say nothing, as it has been written about so often, and is now so well known.

WHITE MAMAN COCHET.—As its name implies, this is a sport from Maman Cochet. It has done well, and is evidently a great acquisition to our white Roses.

PURITY.—An aptly named Rose that appears to me well adapted for pillars and garden decoration. Its colour is pure white when fully open, but faintly flushed with pale flesh during the younger stages.

MRS. FRANK CANT.—In 1897 this was awarded a "card" at the N.R.S., and is a distinct H.P. with silvery white edges and clear pink centre.

MRS. F. W. SANDFORD.—This is a pale blush sport from Mrs. John Laing, and will probably be one of our best light Roses.

MRS. RUMSEY.—Much has been written of this Rose which deserved attention. It is a deep pink sport from Mrs. Geo. Dickson, is mildew proof, and a grand autumn bloomer. It is good either in pots or in the open.

EMPRESS ALEXANDRA OF RUSSIA.—This variety flowered well with me last autumn, and is a free grower. It is of unique colour, rich lake red, orange, saffron, and fiery crimson being all intermingled.—A. PIPER, Uckfield.

METROPOLITAN NOTES.

THE great metropolis possesses countless attractions for country residents, in which even such stay-at-home and duty-serving men as gardeners share, but though the pleasure of "sight-seeing" may form some portion of the programme, yet a horticulturist's beloved and absorbing, though exacting business, always enters largely into the motive and objects of a journey to London. There we expect to find the concentration of all that money, skill, and energy can produce, and in consequence many valuable lessons can be learned on a short trip if the true gardener's eagerness for knowledge be the guiding force. It is the constant demand for up to date information, the desire for advance with the perpetual freshness and varying nature of the subjects which render the horticulturist an eager and life-long student. This is equally true, whether he be an amateur or professional, and if proof were required it were only necessary to point to the horticultural journals, and the wonderful mass of literature devoted specially and solely to the subject.

It is not my intention to enlarge upon the attractions of horticulture, all readers of our excellent Journal are familiar with them, but I will try to record a few of the ideas acquired, and to note what interested me on a recent trip to the great city and its suburbs. Perhaps the first object of attraction to a visitor from a rural district where towns are small, are the shops, and to a horticulturist the florists' and fruiterers' emporiums in the best localities present much to admire, interest, and instruct, if they be observed with "seeing eyes."

At one period of my life a kindly employer gave me the opportunity to visit Paris, a great event in a gardener's career, and I well remember how deep an impression was produced in my mind by the florists' shops and the grove-like, tree-planted boulevards and avenues of that city. The florists' establishments were really tastefully arranged exhibitions of their choicest productions. Scarcely a shop was seen in which bouquets, wreaths, crosses, and vases were not displayed with as much taste and effect as were employed in the individual objects. It was a revelation to one accustomed to the plain, practical methods of the British shop-keeper; it was also a sound lesson, as certainly a beautiful object pays for being displayed to the best advantage. The thought was in my mind at the time that if the dressmakers and milliners have to go to Paris for their novelties in fashions, so, too, might our florists seek for hints in their department.

Some years have elapsed since my travels in French territory, and in that time a great change has taken place in the florists' shops of the metropolis. It is now possible to take a tour through the principal West-end streets and to see as tasteful floral displays as could be wished. The windows are suitably draped with curtains, or what acts as a foil to the colours of the flowers; foliage plants are set here and there in groups or singly, and even loose flowers in stock for use are arranged in vases with the greatest care and skill.

All this means a considerable expenditure in labour and time, and the employment of real artists in flowers to do the work; but it pays, and to a commercial people this, after all, is the test of good work. The principle is the same as that which regulates the sale of imported fruits; all our foreign competitors have found an advantage in sending their wares here well and tastefully packed, tempting to purchasers, and offering a kind of guarantee of value for money. We Britishers have too much of that John Bullism which prompts us to say, as it were, "We offer you a first-class article; take it or leave it, as you like;" and the fact is that many a "first-class article" in consequence is "left" because another is set before us in a more tempting manner, and the vendor seems to be bowing politely and saying, "Honour me by trying my goods; I am sure you will come again."

Many novel and pleasing designs were noted in the objects displayed, but two facts strike one generally as a divergence from past methods. One is the extensive employment of the so-called "Russian Moss," a kind of lichen, for wreaths and crosses, a purpose for which its clear grey colour fits it admirably, and it is certainly an improvement upon the dingy or dirty-looking moss sometimes seen. Large quantities of this lichen are now imported in neat square boxes, and it comes out as clean and fresh as if it had been just gathered; it also lasts for a considerable time without deterioration. Another point is that coloured flowers are much more generally used in wreaths and crosses than formerly. Violets and dark blue Pansies have been commonly employed for long past, but now it is not uncommon to see Roses, or even Orchids, introduced into such designs.

In a Regent Street florist's I saw one of the most beautiful crosses that ever came under my notice; it was about 3 feet high, the ground-work being entirely in large double white Stock blooms, set singly, but closely, and from the centre of the cross arose a most charming cluster of Cattleyas, Lælias, and Dendrobiums, with a few long sprays of Lily of the Valley and Asparagus. The arrangement was most artistic, and rich as the colours were there was nothing garish or offensive to the most fastidious taste, unless colours are objected to altogether.—A COUNTRYMAN.

(To be continued.)

CAMELLIAS IN THE OPEN AIR.

THE hardness of Camellias may be fully perceived by a visit to St. Leonards, Windsor, the residence of F. T. Barry, Esq., which is situated about three miles from Windsor, and commands one of the finest views to be obtained in that district. In the pleasure grounds, irrespective of situation, are planted many varieties of Camellias, of which 280 plants, ranging from 3 to 10 feet in height, occupy a considerable space. Large beds have also been made for the reception of younger plants, and between forty to fifty have been planted this year. Some of these are from seeds that ripened in the open.

The variety Jubilee commenced flowering on January 17th, and L'Insubria January 26th. Morse's Single White is a grand variety, one plant carrying flowers fully 6 inches across. Imbricata rubra, planted nine years ago, forms a splendid specimen 10 feet high and 6 feet through. Five hundred and eighty expanded blooms were counted on this plant at one time, to say nothing of the numerous buds to follow.

The soil consists of a clayey loam with a mixture of decayed leaves. Mr. Brown, the head gardener, says that in planting he makes no exception as regards variety, being fully convinced that they are thoroughly hardy, which the fine habit and vigorous constitution of the plants referred to shows.—H. S., *Dorking*.

HARDY FLOWERS IN OTHER GARDENS.

ROCKVILLE, MURRAYFIELD.

AFTER visiting the Edinburgh Botanic Gardens (page 428), those of Mr. P. Neill Fraser at Rockville, Murrayfield, Edinburgh, were next seen, and fortunately by the time they were reached the rain had ceased. Mr. Neill Fraser's zeal for horticulture is well known, his services for long as Honorary Treasurer, and now as one of the Vice-Presidents of the Royal Caledonian Horticultural Society, having done much to forward it in the North. That his interest in gardening is not confined to promoting its advance in this way is evidenced by the garden at Rockville with its very extensive collection of flowers, shrubs, and Ferns. This has been in process of formation for many years, its owner having kept for about thirty years a garden book containing a record of all the plants added during that time. The garden is beautifully situated on Corstorphine Hill, and commands very extensive views. Its attractions are added to by a sheet of water, which fills an old quarry in the grounds and forms a pleasing feature.

The garden contains a remarkably fine collection of hardy and other Ferns. It was too early to see the outdoor Ferns in their full beauty, but anyone who was an ardent admirer of such plants could not fail to be delighted to see so many rare and beautiful genera, species, and varieties. It is unfortunate that there are so few who grow large collections of the many exquisite forms of the Fern. In the houses were some fine specimens of exotic species, and some of the Filmy Ferns showed how carefully they were looked after by Mr. Fraser and his gardener.

Of more interest to the writer were the flowering plants. These were in great numbers, and occupied a large space. By the margin of the lake is an admirably constructed rock garden, where many alpine were coming into bloom. It was a little too early in the season to see them, but one could observe their growth and their promise of bloom. Aubrietias were fine, and some old waterworn rocks nearer the house were prettily draped with their foliage and flowers. Dwarf Phloxes are numerous, Mr. Neill Fraser having collected all he could procure. This, indeed, seemed to be the rule with other alpine. Even the Cerastiums had not been overlooked, and several pretty species were used with much taste to droop over the large stones.

The most complete collection of Sempervivums I have ever seen was one of the features of the garden. This had been procured from the Continent, and contained 300 species and varieties. Among some there was, as might be expected, a good deal of similarity, but had time permitted an hour or two might have been enjoyably spent in studying these Houseleeks. Saxifragas and Sedums were also very largely represented. One might indeed say the same of every genera of the best alpine. Hardy Orchids, not always seen in collections, were also numerous and thriving.

Among plants in flower was a remarkably beautiful form of *Primula denticulata alba*, of more than usual purity, and especially well formed. *Jeffersonia diphylla* was also very finely grown, and several *Trilliums* showed every sign of being in a congenial place. *T. sessile californicum* was in flower, and Mr. Neill Fraser pointed out a *Trillium* which is unknown to most growers, and has at present no recognised name, although *T. declinatum* is suggested for it. It is of tall growth with pendant white flowers.

Hardy bulbs are very largely grown, Snowdrops, Crocuses, Narcissi, Fritillarias, Brodiaeas, and other genera being represented. Very fine was a border of *Brodiaea (Triteleia) uniflora* close to the house, the superior effect produced by established bulbs being observed in the greater profusion of flower they gave than could be seen on those recently planted. At the edge of the gravel walk they were very vigorous. *Fritillaria citrina* was in flower in one of the rock gardens. Shrubs are largely grown, and a special feature of the garden is the collection of Ivies, which are of great variety and interest.

Primulas are favourites; but a special feature is made of self-coloured Polyanthus, principally white and yellow varieties. This is the strain referred to by the writer in his remarks on the one named John Wilkinson

on page 393 of the Journal, and it may safely be said that there are few strains of equal merit. The best flowers obtainable formed its foundation, and the plants produced were rigorously selected, all inferior varieties being weeded out. The result has been plants of vigorous habit with large pips and trusses, and remarkably uniform in quality. Some splendid whites and deep yellows were among the many plants grown, and one could have spent longer time in more critical examination. Such a garden is a treat to an enthusiast, and the writer hopes to avail himself of the kind invitation to return to see the treasures of Rockville.—S. ARNOTT.

(To be concluded.)

PRIMROSES CHANGING COLOUR.

I USED the term "acaulis," on page 430, as that more commonly used in gardens than "vulgaris," in order that there might be no question as to the identity of the subject in hand, afterwards giving its correct botanical nomenclature in reference to variation of form and of colour by natural cross-fertilisation or hybridisation.

"A. D." says, page 444, that the Cowslip is *Primula veris*, and its red form *P. v. rubra*. I hold that the nomenclature given on page 430 is correct, and that of your correspondent indefinite, *P. veris* being a mere syn. of *P. officinalis*, and *P. v. rubra* of "A. D." identical with *P. variabilis*. I must also demur to the dictum of the Oxlip being but a large coloured form of the Cowslip, for there is no colour but yellow in the true *P. elatior*, a much more uncommon species than *P. variabilis*, the parent of the Polyanthus.

I must also take exception to "A. D.'s" deduction of the change of colour in my Primroses being due to the presence of iron or some other mineral ingredient in the soil without further proof, for on the same formation all the wild Primroses are of the true "primrose" colour in their several generations, never being affected by the natural agents of cross-fertilisation. In the first generation the seedlings come coloured in gardens. Will "A. D." explain that phenomena?

Iron soils are "rare," says "A. D.," but no soil can be or is devoid of iron for the successful growth of any plant. Besides, how comes the grass to be devoid of iron, and the bare soil to show abundance or sufficient to change the colour of both the Primroses and Cowslips, the first in plants and the latter in the seedlings? According to analysis grass land contains more iron than arable, therefore the iron doctrine falls to the ground, as the iron itself has no influence whatever on the colour of Primrose flowers or otherwise, for they cannot be found coloured on soils where the water passing from them is red with oxide of iron. I threw out the hint in that direction simply to induce some of your able chemically instructed correspondents to enter the lists, but I am afraid very little is known of the subject upon any sure foundation.

Half a century ago I planted some wild Primroses in my father's garden, and these all came coloured in flower the following season, while those on the hedgebanks, in copses, and woods remained primrose. The soil there was alluvial, but of the new red sandstone formation. Twenty-five years back I took hundreds from the woods and placed the plants in the garden then in my charge. The flowers all came rosy lilac the following year, and the seedlings from them were still more highly and variedly coloured. That was on the lias formation, where all the Primroses in the glades, copses, and woods were "primrose." Why the variation of colour in even seedlings of transferred Primroses, and no change of colour in the wildings of the square miles of country around?

I may also say that I have had "hands" transferring Primrose roots by the thousand from hedgebanks, copses, and woods to similar positions by woodland walks and glades, but have never found a single instance of change of colour, and that in five different parts of the country, and in two instances in towns. On cultivated soils only do the variations occur, either in the plants first introduced or in their progeny of the first generation, and so far from the change being "rare," I find it invariable, and not unknown even in the Thames Valley. "A. D." admits coloured seedlings; but to what does he attribute the change? Cross-fertilisation will not do, for the same agents must exist around as well as within the precincts of the ground containing the transferred plants, and on this point I think matter for serious digestion and practical value might usefully be adduced by your numerous correspondents.

Allow me to assure "A. D." that I am neither troubled by a bad nor convenient memory, and cannot help facts being indelibly impressed on my mind. Though differing from "A. D." on the point in question I all the same appreciate his many interesting notes, and wish other practical men would follow his example in contributing such varied material to the pages of "our Journal."—ST. ALBANS.

[In an Oak wood of many acres in which the ground is carpeted with Primroses we have occasionally come across a plant, perhaps one out of a million, with dark coloured flowers. We have seen numbers of plants with similar flowers in cottage gardens borne by plants alleged to have been brought from the woods of the common Primrose. This change is fully believed in by numbers of cottagers, but of the assumed fact we have personally no verification. In Mr. G. F. Wilson's interesting woodland garden in Surrey we have seen countless thousands of yellow and buff Polyanthus on one side of a road and coloured forms on the other side. There is presumably the same quantity of iron in the soil on both sides, and this considerable, judging by the redness of the water in the open drains or ditches. Mr. Wilson's opinion would carry weight on the subject in question.]

RHODODENDRON SMIRNOWI.

AMONG dwarf habited species this stands out conspicuously, both on account of its large distinct foliage and big flowers. It is a native of the Caucasus, and at present is little known in this country. Several plants are to be seen at Kew, the largest being about 1½ foot in height, by the same in width. It flowered at Kew for the first time in 1893, and has bloomed freely each year since.

In height it grows very slowly, increasing in width more rapidly, and making a low dense bush. The leaves are about 5 inches long, by 1½ or 2 inches in width, thickly covered when young with a soft white felt, which as the leaves mature disappears from the upper surface, but remains on the under side during the whole life of the leaf. The flowers are rosy lilac, 3 inches across, and produced in loose trusses; the petals broad, with crimped or undulated margins.

Several hybrids have been raised at Kew by crossing this with garden varieties, the object being to obtain a race of large-flowered plants with Smirnowi habit and foliage, and the denser truss and wide range of colour of the garden varieties. The first of the Kew hybrids is now in flower, and hopes are entertained that the new race will shortly be an accomplished fact, as the flowers are exactly intermediate in colour, while the Smirnowi habit and foliage is retained.—W. D.

HORTICULTURAL SHOWS.

MANCHESTER WHITSUNTIDE SHOW.

IT is much to be regretted that the great London show at the Temple should clash with the Manchester Show, for if this were not the case we should imagine that the latter would probably rank as the finest exhibition ever seen, and the thanks of the Mancunians are due to the trade for the magnificent display brought together. Not that the Manchester Orchid lovers suffer very much by comparison, for their collections are quite up to date in all the best known varieties; but such meetings as these help to bring out the very latest, and here the trade certainly are seen to the best possible advantage. As usual, Orchids were in strong force; in fact, the exhibition house was one great display, sufficient to satisfy and engross the attention of connoisseurs for many hours; nor were the Manchester amateurs slow to avail themselves of the opportunity, as evidenced by the great attention paid by the ladies and gentlemen present, and the display was of such excellence as to satisfy the most exacting. When we come to read of the wonderful Temple Show, and to see this great exhibition also, we may well content ourselves with the thought that horticulture is advancing by leaps and bounds, and that each year brings forward horticulturists thoroughly imbued with the true spirit which should dominate them.

Messrs. Sander & Co., St. Albans, although not so largely represented as in former years, were well to the fore with new and rare plants, *Acalypha Sanderi* being much admired, the handsome rosy crimson flowers being in striking contrast to the bright green foliage. *Anthuriums* were large of spathe and well flowered. A giant plant of *Dracæna Sanderiana* was conspicuous, while new Palms were attentively noticed. Some eighteen Orchids were sent by the celebrated Chelsea firm of Veitch, but what of the quality was best judged by the crowded state of the visitors in the vicinity. Every plant was a prize to the fortunate buyers; but one which stood out as the gem of the show, or that has perhaps ever been seen, was the gorgeous *Lælio-Cattleya Eudora* Madame Albert Hye, the splendid hybrid between *Cattleya Mendeli* and *Lælia purpurata*, with rose sepals and petals, giant crimson lip beautifully fringed with gold, and chocolate throat marking. *Lælia purpurata formosa* and *Lælio-Cattleya Ascania* were alike excellent. Messrs. Charlesworth & Co., Bradford, contributed handsomely to the general effect, *Cattleyas Mossiæ* in such choice forms as *Princess*, *Reineckiana*, and other well known varieties predominating. The *Odontoglossums* and *Cypripediums* were also good. Messrs. Jno. Cowan & Co., Ltd., Gateacre, Liverpool, had grand types of *Lælia purpurata*, *Cymbidium* profuse in flower and variety, *Cattleya Mossiæ* very fine, with *Odontoglossums* excellent in every way.

Messrs. B. S. Williams & Son had a bright miscellaneous collection of Orchids and flowering plants, including *Boronias*, *Kalosanthos*, *Ericas*, with foliage plants to complete a capital table. Messrs. Fisher, Son, and Sibray, Sheffield, showed a well cultivated collection of *Crotons* each end of the table, being banked with Orchids. Mr. A. J. Keeling, Cottingley, Yorks, had a small but meritorious display of Orchids, many choice varieties being noticeable.

For the best collection of Orchids in bloom (nurserymen) three competed. Mr. James Cypher, Cheltenham, having a good position, made the most of it, the result being a striking and beautiful picture, the Orchids being of the best. Mr. John Robson, Altrincham, was placed second, the types of *Lælia purpurata* being splendid, as were, indeed, almost the whole of the plants. Messrs. Heath & Son, Cheltenham, had a formal arrangement for third position; but the beautiful *Lælia purpurata* were of such excellence as to demand attention.

In the corresponding section for amateurs E. Ashworth, Esq., Harefield Hall, Wilmslow, gained honours with a collection notable for excellent variety. *Lælia purpurata* in charming light and dark shades, *Cattleyas Schröderæ* and *Mossiæ*, *Cypripediums* and *Odontoglossums* in such fine forms as to almost bewilder. Certainly Mr. Ashworth has never been seen to greater advantage. High culture, good type, and bright flowers were conspicuous in the admirable arrangement staged by A. Warburton, Esq., Vine House, Haslingden, the *Cattleya Mossiæ* being of the best.

Three entered for the best collection of *Cattleyas* and *Lælias* in bloom, Thos. Statter, Esq., Stand Hall, Whitefield, winning with one of his admirable groups. *Lælia purpurata Statteriana*, *Lælia elegans Statteriana*, *Cattleyas Mendeli superba* and *Reineckiana* being grand, as was *Lælio-Cattleya Phœbe*, a chaste and beautiful variety. The second prize went to Duncan Gilmour, Esq., Sandygate, Sheffield, with an extensive and rich assortment. Mr. Thompson of Stone and Mr. F. Hardy, both so well known for their good work, were sadly missed from the *Odontoglossum* class, there not being an entry. For ten specimen Orchids in bloom Mr. Ashworth had in an exceptionally good exhibit of *Cattleya Skinneri alba*, *Odontoglossum Vuylstekeanum*, *Lycaste Skinneri*, and others. Mr. James Cypher was a worthy follower with bright specimens, Thos. Harker, Esq., Didsbury, being third.

The stove and greenhouse plants were also arranged in this house the prize specimens staged in the open class by Mr. Cypher consisting of his grand *Pimeleas*, *Ericas*, *Aphelaxis*, and *Clerodendron*, and in the amateur class by Mr. Wilkes, gardener to Miss Lord, Ashton-on-Mersey, consisting of a wonderful specimen *Dendrobium fimbriatum oculatum*, a fine *Anthurium Scherzerianum*, and *Allamanda grandiflora*. Mr. Wilkes also won with single specimens. Mr. McIntyre, gardener to Mrs. G. Pease, Darlington, won the prizes for six fine-foliaged plants and ten exotic Ferns.

Coming down the rugged steps into the annexe one could not but feel that, with the exhibition house 300 feet in length, and the annexe 400 feet in length, all covered in with glass, there could be no finer place in England to hold an exhibition. If there were one attraction greater than any other, it was the bank of herbaceous *Calceolarias* staged by Messrs. Sutton & Sons, Reading. In it one could find every conceivable shade of colour, both self and spotted; the plants were dwarf and the flowers large. It was without a doubt one of the finest collections ever staged. The Peas, too, came in for their meed of praise; Sutton's Seedling, Productive, and Empress of India showed the advance this firm is making in this direction. Messrs. Clibran & Sons, Altrincham, had an excellent display. The *Violas* were charming, *Calceolarias* very special, whilst miscellaneous plants were thoroughly up to the well-known Oldfield firm's style. Messrs. Dickson's, Ltd., Chester, staged a pretty and interesting display of some two dozen bunches of cut herbaceous flowers, fifty pots of *Violas* and *Pansies*, and it was pleasant to note this firm taking an increasing interest in pot *Auriculas*. The Japanese Maples were of the finest, and were much admired. Messrs. R. Smith & Son, Worcester, deservedly earned the gratitude of all visitors by their superb *Clematis* in pots. The *Boronias* formed a pretty edging. It was worthy of the firm's reputation. Mr. J. Waterer's *Rhododendrons*, planted out and in pots, were worthy of all admiration. Mr. Wilkes won with *Calceolarias* and *Cinerarias*, while J. Brown, Esq., Roses in pots were capital, and thoroughly worthy of the prize awarded. Messrs. W. & J. Birkenhead's hardy Ferns were so beautiful as to make one wonder why their cultivation is not more generally taken up, for they certainly put to the blush many of the exotics.

The groups of plants were up to the usual Manchester standard. For nurserymen, Messrs. R. P. Ker & Sons, Aigburth, Liverpool, won the award handsomely. The arrangement was light and faultless, their beautiful foliage plants, chiefly *Crotons*, being most telling. Mr. A. J. A. Bruce, Chorlton-cum-Medlock, was little behind, the flowering plants being judiciously distributed. Mr. Bruce also won with a choice bank of *Carnations*. Mr. Wilkes again proved his ability in the local group of 100 feet, and was second to Mr. McIntyre in the 200 feet, the latter winning the first prize with a superb group. The second prize in the 100 feet was taken by Mrs. Jno. Fielden, Dobroyd Castle. W. H. Thorley, Esq., Chorlton-cum-Hardy, won with fair *Zonal Pelargoniums*; and Mrs. Blair, Whalley Range, with twelve *Gloxinias*. Table plants were effective, but bouquets were poor.

In addition to numerous first-class certificates and awards of merit, gold medals were awarded to Messrs. Sander & Co., St. Albans, for Orchids and new and rare plants; Fisher Son & Sibray, Ltd., for *Crotons* and Orchids; Sutton & Sons, Reading, for *Calceolarias*; J. Veitch and Sons, Chelsea, for their *Lælio-Cattleya*, mentioned elsewhere; and Sir Trevor Lawrence for *Cypripedium Olenus*, a grand dark spotted variety, very much admired. Silver medals were awarded to Messrs. Charlesworth & Co., Heaton, Bradford; J. Cowan & Co., Liverpool; and A. J. Keeling, Bingley, Yorks, for Orchids; B. S. Williams, for Orchids and plants; R. Smith & Co., Worcester, for *Clematis*; J. Waterer, Bagshot, for *Rhododendrons*; and A. J. A. Bruce for *Carnations*.

Thomas Statter, Esq., Chairman of the Council, occupying the chair in the absence of the Earl of Derby, spoke of the hopeful state of the Society. He emphasised the importance of the Press in helping forward the good work of all such societies by trying to get the public to attend, and mentioned the interesting fact that the large amount of money given in prizes had all been provided heartily by members of the Council. To Sir Trevor Lawrence, Bart., he, in the name of all present, gave a hearty welcome on his first visit to Manchester that day, and expressed the hope that he might oftener come amongst them. Sir Trevor, in reply, thanked all present for their sincere welcome. He was greatly surprised at the splendid show that day. He emphasised the importance of the highest knowledge being brought to bear in the pursuit of gardening, believing that the scientific gardener will be the one preferred to that of the rule of thumb. The healthy state of the R.H.S. was mentioned with pleasure, Sir Trevor concluding by saying how delighted he had been with the grand show and his first visit to Manchester, and promising to be amongst them again in the near future. Professor Leo Grindon proposed the toast of the Society, and Mr. Tait that of the Judges, Mr. Owen Thomas and Mr. Gribble responding. Mr. P. Weathers, the Curator, appears to be

the right man in the right place, and his unfailing courtesy, coupled with that of Mr. Paul, his assistant, render the Manchester Shows most enjoyable. The gardens are in splendid condition, but more of these anon.

BATH AND WEST OF ENGLAND.—MAY 25TH TO 30TH.

THIS Society, under the presidency of the Right Hon. the Lord Windsor, held its annual show in the Cathays Park at Cardiff, in ideal weather, and proved in every particular a magnificent exhibition. The metropolis of Wales is singularly fortunate in having such an admirable site as the Cathays Park for this purpose, for being in the centre of the town it enjoys the facilities of close proximity to railways and hotels, while its sixty odd acres possess the sylvan and rural beauty so essential to a happy display of things pertaining to agriculture. Though an agricultural show, it was that and something more, for its horticultural section was an attraction in itself, and well worth a visit.

Undoubtedly from a point of effect of arrangement the pavilion devoted to floral and plant exhibits was the prettiest that has been seen in Wales for years, eclipsing in many ways the shows of the Cardiff Horticultural Society. In accordance with the usual custom of this Society no prizes or certificates were given to horticultural exhibits, thus causing it to be solely supported—with the exception of Mr. A. Pettigrew, gardener to the Marquis of Bute—by nurserymen and florists in the trade. Though exhibits one and all were admirable and tastefully arranged, yet without a doubt the finest and most attractive display was an arrangement of Carnations exhibited by Messrs. Cutbush & Son, London. It occupied a place of prominence at the extremity of the pavilion, and being designed on the ground level, was seen to its very best advantage. As a background, Palms, Bamboos, and Crimson Rambler Roses were arranged, while Cocos Weddelliana and Adiantums were tastefully interspersed. The Princess of Wales and Old Blush Malmaisons were very striking and in perfect form, while Germania and La Villette were irresistibly attractive. A well-flowered plant of the new Malmaison Madame Adeline Patti elicited unbounded admiration from Carnation enthusiasts who had the opportunity of inspecting it.

Another very attractive and interesting exhibit was that staged by Messrs. Paul & Son, Cheshunt; the cut flowers of their sweet-scented unnamed Rhododendrons, and their named novelties of double and single Lilacs, were the feature of the stand. The former, offered for sale for the first time at this show, are really very fine, and cannot fail to commend themselves in every way to lovers of Rhododendrons, for in delicacy of colour and form and in fragrance their flowers are delightful. The Lilacs, especially the white alba grandiflora and the Centranthus rubra-like flowers of Madame Krentes, Philemon, and Souvenir de L. Spathe were very striking. These novelties, whilst possessing a marked richness of colouring, appear to retain the habit and peculiar gracefulness of the old Lilacs. Besides Rhododendrons and Lilacs, Paul & Son exhibited a very fine collection of cut perennial flowers, and also a lovely specimen of the new Polyantha Rose "Pschye," its light pink flowers delighting and captivating everyone.

Messrs. R. Veitch & Son of Exeter, in an exceedingly interesting collection, exhibited some very fine Bamboos, amongst which Phyllostachys castillonis was conspicuous with its polished green and yellow zigzagged stem. Messrs. Garaway & Co., Bristol, exhibited in a collection of miscellaneous plants two good examples of Acalypha Sanderi—quite a novelty, at least in South Wales—the red drooping spikes of flowers, resembling those of Love-lies-bleeding, standing out well against the dark green foliage, making them prominent objects in the floral tent. A new white Carnation, George Brooks, in this stand, gave every promise of becoming an acquisition.

An intensely pretty arrangement was that staged by Messrs. G. Cooling and Sons, Bath. Their boxes of cut Roses were particularly nice. Mr. W. J. Godfrey of Exmouth staged a gorgeous display of Pelargoniums, and Messrs. Laing & Sons of Forest Hill a fine collection of stove plants, and Messrs. Barr & Son alpine plants and herbaceous flowers. Amongst local exhibitors Mr. William Treseder, Cardiff, was in evidence with his stands of cut flowers, the bouquets, wreaths, and crosses being magnificent expositions of tasteful art. Mr. Ralph Crossling, Penarth Nurseries, showed a collection of well grown foliage plants, with Cannas in flower happily intermixed to lighten it up.

As previously noted, Mr. A. Pettigrew, Cardiff Castle Gardens, for the Marquis of Bute, was the sole one outside the trade who contributed to the success of the horticultural section. The group occupying the most prominent central position of the Pavilion was admirably arranged, giving a most desirable light and airy effect. The centrepiece was a splendid specimen of Areca lutescens, while around were arranged graceful Palms, well coloured Crotons, Dracænas, and Pandanus, with a variety of flowering plants, amongst which Arthropodium cirrhatum was conspicuous with its graceful pendulous orange-like blossoms appearing to impart its lightness to the entire group. Adiantum cuneatum, Isolepis gracilis, and Panicum afforded a suitable and agreeable finish to the whole. W. Herbert Fowler, Esq., the Secretary of the horticultural department of the Bath and West of England, is to be complimented upon the success of the show, which will be long remembered by horticulturists and lovers of flowers in the principality.

Messrs. Webb & Sons, Wordsley, Stourbridge, have a display which fully sustains their reputation for the superiority of their seeds, seed corn, and special manures. Among the many exhibits are fine Mangolds of last year's growth, Webb's Imperial Swede, Grasses and Clovers in growth, and also dried specimens, cereals in the ear, and samples of grain of fine quality, comprising all the firm's Wheats, Barleys, and Oats.

Vegetable and flower seeds were well represented by examples of Cabbage, Broccoli, Radish, Lettuce, and a collection of Calceolarias. A large number of dishes of Potatoes was also staged, and included such as Stourbridge Glory and New Motor. Webbs' special manures for all crops were shown, as also were samples of the raw materials from which they are made.

THE YOUNG GARDENERS' DOMAIN.

IN THE KITCHEN GARDEN.

MUCH is required to be done in the kitchen garden, especially after the late genial showers of rain. Bush fruits, Gooseberries, and Currants, Strawberries, Figs on walls, and all stone fruits, give promise of excellent crops—except Apricots. These will be a failure in some gardens, in spite of the covering afforded them, owing to the severe weather experienced while the trees were in bloom. Wall trees will be benefited by a mulching of good farmyard manure, the nourishing properties of which will be washed down to the roots by the rain. Should the season prove dry, give thorough soakings of liquid manure or clear water through the mulching, which may be renewed once or more during the season, as it becomes exhausted. Let the removal of the old material and the application of the new be done at the same time, otherwise many valuable roots, which have been enticed to the surface, will perish, and may result in the loss of a crop of fruit.

Asparagus, Veitch's Model Broccoli, Ellam's Early Cabbage, summer Spinach, forced Carrots, Potatoes, Turnips, and Vegetable Marrows, are the chief vegetables for present use, and these will carry us on until Peas, Broad Beans, Early Erfurt, and Early London Cauliflowers come in. Veitch's Early Peas are in full bloom, with Chelsea Gem to follow. Broad Beans of the Windsor type are well advanced, and with favourable weather will soon be in full bloom. Parsnips have received their final thinning to 9 inches apart. Carrots are partially thinned, the final thinning being deferred until the young roots are fit for use, when they form an excellent dish. The continued use of the hoe between small crops greatly assists them to grow, by allowing the air to pass down to the roots; moreover, the maintenance of a loose surface tends to keep the soil moist during dry weather. The apparently simple operation of hoeing is acknowledged by the best gardeners and market growers to be work of first importance.

The last ten days have been favourable to the planting of Lettuces, Cabbages, and other plants from frames and hotbeds. Celery trenches may with advantage be formed and prepared at once by forking in them a liberal dressing of rich farmyard manure. In deeply worked ground the surface of the trenches when ready for planting may be 6 inches below the general level; if the land is shallow 2 inches suffice. For large-growing varieties the rows may be from 4½ to 5 feet apart, according to the depth of the trenches; for dwarf varieties 3 feet. The spaces between may be used for Lettuces, Radishes, or any crop which can be cleared off before the soil is required for earthing the Celery. Successional sowings of Peas at fortnightly intervals, or as soon as the plants from the previous sowing appear through the ground, maintain a regular supply.

Asparagus beds will be found to yield better produce if an application of 2 or 3 ozs. of salt, or half the quantity of nitrate of soda to the square yard be given them, to be washed-in naturally or artificially. It is desirable to cut all the heads that are large enough daily, and if not required for immediate use tie in bundles of twenty-five, and place the ends in saucers of water in any convenient place. If the heads are allowed to extend and mature early in the season the period of cutting is shortened, whereas in most gardens it is desired to prolong the supply as far as possible. The bedding of Strawberries is often deferred till the fruit changes. The litter can be much more quickly spread between the rows before the fruit trusses bend over, and it also conserves moisture, which is important when dry weather sets in early in June.—T. P.

CLEAN versus DIRTY POTS.

I HAVE waited some time in the hope that some gardener older and abler than myself would notice a remark made by Mr. Buchanan in his article on "Profitable Fruit Growing," page 364. It is as follows: "Clean pots are not necessary for healthy growth." Oh! shade of the dear old gardener with whom I was apprenticed; well is it for thee that thou didst not live to see the day when such practices were recommended in thy beloved Journal!

Mr. Buchanan goes on to say that he has "never seen any inconvenience arise from the use of dirty pots." I am but a young man, and it may seem somewhat presumptuous in me to differ from one who is probably old enough to be my father, but I must say that my experience is utterly opposed to his. On the day just closed I have been transferring Cinerarias from small into larger pots. I noticed that where the pots had not been thoroughly cleaned there was great difficulty in knocking out the ball of soil with roots intact; and from all that I have ever read or heard from gardeners of good standing, this is the general experience.

Speaking personally, I would as soon don a dirty shirt after a bath as put a healthy plant in a dirty pot. Perhaps this is owing to my youth, and I may see fit to alter my opinion on this subject as I grow older, but with all humility I trust I may never forget the good old adage, "Cleanliness is next to godliness."

If Mr. Buchanan's dictum be true, it makes one blush to think of the weary waste of time going on daily in thousands of gardens throughout the kingdom; and I add, had the various gardeners under whom I served

been of Mr. Buchanan's opinion, I should have been saved many a weary day at that back-aching job—pot-washing.

It would interest me to know what "An Old Boy" thinks of such advice as Mr. Buchanan's, because he has, in the admirable series of articles which he has from time to time contributed to the *Journal*, always insisted on the necessity of doing things thoroughly. As I said before, I may be wrong in my conclusions, but, with all due respect to Mr. Buchanan, there is nothing very thorough or workmanlike in potting plants in dirty pots.

His statement on this point reads very peculiar when compared with his advice to young men on pages 340-41. What is one to think of such sentences as these? "Get your whole heart into your work." "Have an ambition to excel." "The greater part, if not the whole of success, is made up of strict and intelligent attention to every little detail connected with the thing you wish to accomplish."

All this is excellent; but, in my humble opinion, its value is considerably discounted when taken in conjunction with the advice to use dirty pots.—A YOUNG ROSS-SHIRE GARDENER.

[We have often heard one of the most accomplished growers of specimen Heaths, and other hardwooded plants of past years, aver that he would as soon eat his dinner off a dirty plate as place in a dirty pot.]

HAMPTON COURT.

HAVING recently paid a visit to this interesting old place, perhaps others of the "Domain" would like to hear something about it. On leaving Hampton Court station a turn to the right brought us at once to the bridge over the Thames, whence a good view of the Palace is obtained; a stately pile, indeed, for it covers an area of nearly eight acres.

Entering the grounds by the Trophy Gates, within which, on the left, are the military barracks facing the courtyard, through which we passed to the Great Gate House of Wolsey's Palace. Inside the Great Hall are some of the most beautiful tapestries in the world, illustrative of Scriptural history, also the immense coloured glass windows, representing arms, badges, initials, pedigrees, English history, and other interesting matter. Ascending the King's Great Staircase we reach the State rooms and view the splendid pictures by renowned artists; the paintings on the ceilings were very attractive, and displayed great skill. Charming views of the gardens, the Thames, and the surrounding country are obtained from the windows of these rooms, and being the middle of May the Lilacs were in their full beauty, while deciduous and evergreen trees and shrubs were clothed in their summer garments. The different shades of green at this season were very noticeable. The grand old Yews presented a pleasing contrast to the light green of deciduous trees. Rhododendrons and Azalea mollis were rapidly expanding their blooms. The herbaceous borders were gay both with flowers and foliage. Spring bedding was at its best. The Chestnuts—the pride of Bushy Park adjoining—would be fully expanded in about a week from the time of this visit.

Before concluding I must mention the great Vine, which no gardener ought to miss. Here, indeed, is a giant which could not be met with elsewhere. The vinery enclosed an area of 2200 square feet. The circumference of the Vine stem is $3\frac{1}{2}$ feet, and the entire roof was evenly covered. The bunches were fully formed, and produced at regular intervals, the crop averaging 1200 bunches of about half a pound each. Everything was very neat and clean. I watched my opportunity to ask a few questions of the attendant at the door, and learned that its border was entirely outside, and extended to a wall 60 to 70 feet distant. To reach this the roots passed under a gravel walk and grass verge from 12 to 15 feet wide. The ground was kept clear of all vegetation with the exception of a few bulbs and a herbaceous border about 6 feet wide next the wall. The Vine is fed frequently with bonemeal, and is remarkably clean from all insects. The Vine is nearly 130 years old, and the glass structure has been several times renewed and enlarged during that time. No artificial heat is used. I should have liked to learn more, but other visitors claimed attention. Passing to the east and south front of the Palace, through the "Wilderness," we made our exit through the Lion Gates, having fully enjoyed and learned much in the few brief hours spent at Hampton Court.—F. L. T., *Burwood*.

BORDER POLYANTHUSES.—The past winter and spring have been most favourable for these plants. Never before have I seen them flower so strongly or so continuously. Seedling plants raised towards the end of August produced a wealth of colour and variety in the seed bed—quite an unusual experience. Judging from reports which have appeared of late, these have not been exhibited in a condition to satisfy the florist's standard; but for border furnishing and for cutting purposes the florists' ideal is not strictly necessary. For massing there are no colours more effective than the bright orange and yellow shades. Beds and borders filled with these are conspicuous even at a long distance, while the darker self and bizarre shades need to be examined more closely. All are well worthy of a larger share of patronage. Once a strain is secured, it is easy to maintain and improve the stock by selecting the best, and planting them in an isolated bed, where they may flower and mature their seed crop. Seeds sown as soon as ripe will give strong plants to prick out in the spring, which, with a summer's growth, are in first rate order for the flower garden beds in winter. For furnishing the edges of pleasure ground borders they are best put direct into their places in the spring.—R. A.

FRUIT FORCING.

Vines.—Early House.—As soon as the Grapes are cleared off the Vines give the inside borders a thorough supply of liquid manure, or a top-dressing of some fertiliser washed in. This, with adequate, but not excessive, supplies of water, will help to plump the buds and encourage root action, so essential to the activity of the laterals, which, if allowed moderate extension, is the best preventive of premature ripening of the foliage. Keep the ventilators open constantly, even in cold weather. Syringe thoroughly, to cleanse the foliage of dirt and insects, and repeat occasionally, or as found necessary, to keep the old or main leaves healthy. Fresh laterals will soon be produced, and cultivators should maintain an even growth over the Vines, pinching the gross laterals and encouraging the weak. The mulching or covering having been removed from the outside border, with just enough of the lighter part left to protect the roots, a watering with liquid manure may be given, but this will not be needed where rain in sufficient amount has recently fallen.

Second Early House.—Vines started at the New Year have the Grapes ripening where they have been brought forward gently, but when grown rapidly the crop will be ripe. Maintain a circulation of warm, rather dry, air constantly, increasing the ventilation early. Keep the floors damped on hot days, allowing the temperature to fall to 60° at night when cold, or 65° when warm, with sufficient heat in the pipes to prevent moisture condensing on the berries. If there is likely to be any want of finish allow the Vines time, by giving as long a rest at night as possible. Moderate moisture, even after the Grapes are ripe, is essential to the health of the foliage, hence damping the floors and stages must be resorted to occasionally. Allow a moderate extension of the laterals, to encourage root action, but keep gross growths in check, so as to cause an equal distribution of the sap. When ripe a minimum temperature of 60° will be sufficient.

Early Muscat Houses.—The fruit ripening will need a drier condition of the atmosphere, but avoid great aridity, or the foliage will fall a prey to red spider. Do not allow any deficiency of moisture in the borders, for Muscats are gross feeders. The supply of water to the roots will in some measure compensate for the drier condition of the atmosphere. Provide a circulation of air constantly, preventing the moisture condensing on the berries by sufficient warmth in the pipes to insure a changing atmosphere. Lateral extension is the best safeguard against shanking at this stage, along with a steady temperature. Keep the night temperature at 65° to 70°, 80° to 85° by day with a little sun, and 90° to 95° with it in full force. Ventilate early, and regulate by the sun's increase, and so with its decline. The old leaves of Muscats are liable to be scorched under powerful sun after a period of dull weather. In very bright weather draw a single thickness of tanned netting over the roof-lights, which, without impeding too much light, will prevent the scorching.

Midseason Houses.—Vines in these will be in various stages of development, according to the time of starting. Those that have stoned will be swelling the berries fast, and the borders should have a top-dressing washed in, or a supply of liquid manure, repeating with pure water or stronger food as necessary. Admit a little air constantly at the top of the house, and ventilate freely in the early part of the day, closing early with sun heat and a genial condition of the atmosphere. Fire heat will only be necessary to secure 60° to 65° at night, and 70° to 75° by day, keeping through the day at 80° to 85°, and closing sufficiently early to run up to 90° or 95°.

Grapes Stoning.—During this process the Vines should have a regular temperature of about 65° at night, and 70° to 75° by day from artificial heat if the Grapes are wanted by a given time. Admit air in good time, always a little at 70°, and dissipate moisture before the sun acts powerfully upon the foliage. Allow a moderate lateral extension, but avoid overcropping, and supply a top-dressing (washing-in) or liquid manure.

Grapes Scalding.—Muscats and Lady Downe's, with other varieties, are liable to scald in the later stages of stoning, therefore must be watched in hot bright weather, and air admitted more freely for a fortnight or three weeks, until colouring commences. Muscats are sometimes scorched when exposed to the direct rays of the sun, even after colouring has commenced, which must be provided against by a little extra ventilation, especially early; and in bright weather a slight shading. Black Hamburghs also occasionally are scorched when the berries are exposed whilst damp to the direct rays of the sun, which can mostly be avoided by a good spread of foliage, or by a bountiful supply of air by day and a little ventilation constantly at the upper part of the house, with a genial warmth in the hot-water pipes, being very particular as regards early ventilation.

Late Houses.—Late varieties of Grapes in flower must have a circulation of rather dry, warm air, and a temperature of 70° to 75° at night, rising to 85° or 90° from sun heat, as without this the thick-skinned varieties do not set well. Thin the berries freely as soon as they are set, but this, in the case of shy-setting varieties, must be confined to the removal of the smallest and imperfectly set berries in the first instance, deferring the general thinning until the properly fertilised berries can be determined by their free swelling. There must be no deficiency of moisture at the roots.

therefore afford liquid manure copiously after the Grapes are thinned and swelling, or a top-dressing may be given of some approved artificial manure, distributing it evenly on the surface, and washing it in with tepid water after the border has been duly moistened, this being done prior to the application of the fertiliser.

THE KITCHEN GARDEN.

Celery.—The plants move badly after they have become drawn by standing too closely together in boxes, frames, or beds. Carefully transplanted to the trenches or beds ere they press against each other, no perceptible check to their growth will be observable. Before moving them give a soaking of water to the roots, remove sucker growths and the smallest leaves, and replant firmly. A watering will settle the soil about the roots, and a covering of Pea stakes affords some protection against frost, cold winds, and strong sun. Late-raised plants directly they are large enough should be pricked out in nursery beds to prepare them for the trenches.

Broccoli and Brussels Sprouts.—A number of plants of Veitch's Autumn Broccoli and Brussels Sprouts put out now should produce profitable crops at a time when vegetables are becoming somewhat limited in variety. If raised thinly in seed beds they may be drawn from these and replanted with a dibbler, but in most gardens the early plants are raised under glass, pricked out on sheltered borders, and are transplanted to their final quarters with the aid of a trowel. If the rows of short-topped early or successional Potatoes have been disposed 3 feet apart, and duly moulded, these may be advantageously cropped between with early Broccoli and Brussels Sprouts, but it is a mistake to plant between stronger growing Potatoes unless the rows of these are 42 inches apart.

Ridge Cucumbers.—These succeed well during hot summer, but are liable to fail if a cold wet time is experienced in June and July. A great heap of manure is not the best position for them, as this, when decayed, becomes sodden and destructive to the roots. Late-raised plants established singly in small pots are preferable to any raised earlier. Put these out 3 feet apart on ridges prepared as for Vegetable Marrows (see below), doing this early in June. Protect carefully from cold winds, allow the plants to branch naturally, and peg down the leading growths.

Vegetable Marrows.—These are more productive grown either on ridges or dotted about on well-manured ground than on heaps of manure. For ridges, select a sunny open spot, sheltering if necessary, and mark out a space 4 feet wide and of any length, distribute 6 inches of the soil on each side, wheel into the trench a depth of 12 inches to 18 inches of hot partially decayed manure, and return the soil, with a little added from the alleys to the top of this. When the heat from the manure and sun has well warmed the soil, put out the plants in a single line through the centre and 3 feet apart. Protect with hand-lights, cloches, or other contrivances, removing those not glazed every morning. Putting out strong, late-raised plants during the last week in May or first week in June means an early crop, but good results attend the practice of sowing a few seeds on the ridges. This may be done now or a week later.

Tomatoes in Sheltered Positions.—Tomato plants are hardier than is generally supposed. Seeing also that a gain of a week or more may make all the difference between success and partial failure no time should be lost in planting. If during the first fortnight the plants do not appear to make any progress the roots will yet have made a good start, and instead of the first cluster missing to set it will most probably be saved. Any vacancies between fruit trees on south walls should be utilised for Tomato culture, and also sunny house and shed walls, fences, and temporary hoardings. A very rich root run is not good for open air Tomatoes. It causes them to grow too rankly; but the other extreme should also be avoided. Mix a little fresh loam and well decayed manure with the ordinary garden soil, and a sprinkling of some special manure. The plants should be in a moist state at the roots when turned out of their pots, and be planted firmly 12 to 15 inches apart and confined to single stems, or from 18 inches to 2 feet apart if scarce, laying in two leaders in this case. No particular varieties can be said to crop much better than others in the open: but the preference may well be given to those known to ripen early. See that the old balls of soil and roots do not become injuriously dry during the first month after planting, and if any kind of protection can be afforded that will favour early cropping.

Planting Tomatoes in the Open.—In this instance it only pays to plant varieties that produce slightly ribbed or non-cracking fruit, and which also commence ripening early. Select a sunny open breadth of ground, sloping to the south for choice, and prepare as for Potatoes; some growers planting among dwarf early sorts of the latter. Plant out late in May, or not later than the first week in June, an early start being imperative, arranging the plants 15 inches apart, in rows 3 feet asunder. Sturdy little plants out of 3-inch pots are preferable to larger ones, and these can be protected, if need be, by 6-inch pots inverted over them on frosty nights, taking the precaution to place a clod of earth over the drainage hole.

WALLFLOWERS.—The rich fragrance and beautiful display made by these plants for some time past remind one of the need for sowing seeds for the next year's uses. Some will have already done so but there is no gain in getting such forward plants—indeed, for flower garden work, which entails so much labour in lifting and replanting in the autumn, there is an all-round disadvantage in having plants so large to deal with. The month of June is quite soon enough to sow, so that there is yet time for those who have not ordered their seeds to do so for immediate use. There are many sorts to choose from, in both yellow and dark forms.—S.

THE BEE-KEEPER.

TIMELY ATTENTION.

THE importance of giving timely attention to all stocks in the apiary during the present inclement weather will be acknowledged by all bee-keepers. The much-needed rain having fallen in abundance, warm days and bright sunshine are now required for all growing crops, and will be equally welcome to the bees, as the all-important factor, the weather, combined with good management, makes all the difference between success and failure in bee-keeping.

Bee-keepers in the Midland and Northern counties escaped the severe gale which did so much damage to the bees in the South and West of England. "S. T.," writing on the 10th inst., says, "On May the 2nd the bees were flying in great numbers; the day was mild, but a high wind was blowing, which increased to a gale. The bees came homewards in thousands, but the majority of them dropped short of the alighting board and there they lay in heaps under each hive; thousands of bees must have been lost from my apiary alone. Although I have been a bee-keeper for many years I have never seen the like before. Being anxious to see how others had fared I walked two miles to see another bee-keeper who farms bees extensively; there I found the same thing had happened, and from inquiries made I find that all bee-keepers throughout this district have suffered from the same cause." Fortunately such a serious state of affairs as this does not often happen. Bees are beaten down during the prevalence of high winds and heavy thunderstorms; but if the weather is mild, and the sun comes out again, it is surprising how quickly the bees recover and are enabled to reach the hive in safety.

The same writer says, "Here we have some large wild Cherry trees in the woods, which are at the present time truly a magnificent sight. What a harvest for the bees! The fruit trees, too, in this district (the West of England) are grand, and there is every promise of abundance of fruit. Plums and Damsons have set well; Peaches and Nectarines outside will be a thin crop, Cherries grand; Pears, I think, have set well. Apples are now a mass of bloom, which, thanks to the bees and fine weather, will probably be the crop of the season." The above, being written by a close observer, is interesting to gardeners as well as bee-keepers residing in other districts, as showing the state of the crop as well as the condition of the bees in a noted fruit-growing part of the country.—AN ENGLISH BEE-KEEPER.

SWARMS—DEAD DRONES.

I AM a beginner with bees. I have two skeps, one old and the other a swarm of last year, about May 20th; a fairly good one then, I thought. I have fed them as advised in the Journal, and found them increase rapidly. I am expecting them to swarm every day. Both skeps work equally well, and I watch them a good deal at times. On 22nd I noticed ten drones pass in the hive in a minute; to-day (23rd) I saw seven and sometimes nine drones on the alighting board at one time, besides some going in and out. Is it at all unusual? Some days I pick up two and three dead drones under the hive, and once as many as eight in one day. Do you think I have any cause to be anxious at seeing so many? The old skep does not seem to have very many drones passing in and out. I do not feed them now. I am enclosing what I call drones, if I am not mistaken; there are three, and one of the workers. Could you tell me what sort they are, or what they are called by name. I might also mention that I often find very large white grubs, what would eventually be drones I should think, outside dead.—ONE IN NEED.

[The bees forwarded by "One in Need" are, as he surmises, three drones and one worker of the native brown or black bee, *Apis mellifica*. It is interesting to learn that his bees are doing well, and that they are on the point of swarming from straw skeps. It is quite a common occurrence to see the drones passing freely in and out of the hive at this season when they become crowded with bees and are on the point of swarming. One hive having more drones than the other is owing to the fact of there being more drone comb which the queen has filled with eggs. Some queens are greater drone breeders than others. In frame hives they can always be kept down within reasonable limits by using full sheets of brood foundation. Our correspondent need not be alarmed at finding dead drones outside of the hive, whether they are fully developed or in a grub state, as during a spell of cold, dull, showery weather, such as has been experienced of late, the bees will at once commence to turn the useless members (for the time being) out of the hive. They will do this, although there may be abundance of stores in the hive. If, however, worker brood is turned out it is a sign of starvation, and they should at once be supplied with stores. The 2 inches of open space round the outside of the frames in a frame hive will be better if not packed with any material before autumn. The hive will be cooler in consequence.]

TRADE CATALOGUE RECEIVED.

R. H. Bath, Ltd., Wisbech.—*Dahlias and Bedding Plants.*

TO CORRESPONDENTS

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **8. Rose Hill Road, Wandsworth, S.W.**, and **NOT** to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Seedling Gloxinia (Flora).—The flower is good, rich crimson in body colour, and clearly spotted round the edge. The variety is worthy of preservation and increase for home decoration, but is not sufficiently distinct from, and superior to, others in cultivation to possess appreciable commercial value, though it is above the average merit of seedlings.

Stopping Melons (Melon).—If by the top of the pit you mean top of the trellis it is best to allow the leading growths to extend about two-thirds across it, or on a 6-foot wide trellis 4 feet to 4 feet 6 inches, and then pinch off the end when quite small. This will throw the vigour into the laterals, and give rise to plenty of them for fruiting. The laterals may be stopped when the blossoms are fertilised one joint beyond the show for fruit. If no fruit show at the second or third joint of the laterals stop them at the third leaf, so as to cause sub-laterals and a plentiful show of flowers for setting and insuring a crop of fruit.

Chrysalis of Insect (J. C.).—The pupa appears that of the puss moth (*Dicramera vinula*), the caterpillar of which has a very singular appearance by its two tail-like appendages, and when disturbed placing itself in a fighting attitude. It constructs the very singular cocoon out of bits of bark or wood, glueing them together and forming a protection for the winter, in which it changes into pupa as forwarded. The moths usually appear at the end of May or the beginning of June. The spray, much dried, appears that of *Euphorbia cyparissias*, useful for greenery in arranging flowers in vases.

Carnation Leaves Diseased (P. J. P.).—The spots on the "grass" are the pustules of the rust fungus (*Uromyces caryophyllinus*). It first appears on the leaf or stem as a pale elevated pustule, over which the epidermis soon breaks, hanging on the edges in a ragged condition, and reveals a brown powdery mass, which consists of the reproductive spores of the fungus. These bodies (uredospores) are those by which the disease is rapidly propagated and spread. To prevent this the plants may be dusted with an advertised fungicide in powder, such as fostite, this being less objectionable than Bordeaux mixture, but both have a deleterious effect on the roots unless very carefully used. We use permanganate of potash, half ounce to a gallon of water, applying with a sponge to the affected parts, a very tedious but effective application. For spraying purposes sulphide of potassium, half ounce to a gallon of water, answers well, or it may be applied to the pustules with a sponge, afterwards spraying as a preventive. Serious infestations are beyond cure.

Propagating Hardy Azalea (W. T.).—From your description of it the variety is probably one of the innumerable Ghent Azaleas which originated by crossing the Turkish *A. pontica* with certain American species, and the intercrossing of resulting varieties. If seed ripens we should sow some in sandy peat in pots or boxes, as it is possible several plants may come true. Well chosen cuttings of the previous year's wood, 2 or 3 inches long, taken with a heel, and inserted in sand about the end of August, emit roots. They must be covered with a hand-light and kept somewhat close for about two months, and at the end of that time air should be gradually given and increased. Layers, mossed and well pegged into free gritty soil in March, produce roots, but should remain in position two years before being separated. Owing to the proneness of several varieties to canker on their own roots, they are usually increased by grafting on stocks of *A. phoenicea*, raised from cuttings and established in small pots for the purpose. They may be side grafted in a close case in spring or summer. These, under good management, make the most satisfactory plants.

Diseased Tulip Leaves (W. W.).—The leaves are affected by the spot fungus (*Botrytis galanthina*), which is rather prevalent this season on liliaceous plants, especially *Liliums*. It seldom does more than hasten the decay of the leafage of Tulips, and so far as we know does not materially affect the bulbs unless left in the ground from year to year, and even then we have not found much harm result if a dressing of quicklime be applied after the tops are cleared away. Of course it is the mycelial form that affects the bulbs and passes over from year to year by the sclerotia from which spring the final stage, called *Sclerotinia bulborum*. Burn the tops, and use quicklime slaked as a top-dressing, about $\frac{1}{2}$ lb. per square yard sufficing, pointing very lightly in.

Strawberry Leaves Scorched (Salopia).—The leaves are "scorched" through moisture having been condensed on them, and then air admitted, perhaps too late, and so freely as to cause speedy evaporation. We have known many similar cases, especially with luxuriant plants, the moisture hanging on the edges of the leaves, causing the destruction of the tissues. There is no disease; a little heat in the pipes, and a circulation of air constantly by leaving a chink for top ventilation all night, with timely attention to increasing it early in the day, being the best preventive. Such occurrences are the most prevalent after a continuance of cold, dull weather, and on a return to bright days, the precaution not having been taken to meet the changed circumstances by early ventilation.

Increasing Bulbs (Evesham Gardener).—The scales of bulbs are flattened leafstalks, and at their base are latent buds. On slicing off the end of a bulb, just above the ring from which the roots issue, some at

FIG. 88.
PROPAGATING HYACINTHS.

least of the parts containing such buds are brought in contact with the soil in which the bulbs are embedded, and if this is very sandy bulblets form and attain the size of large peas the first season, and develop into flowering size in three or four years. We have seen Hyacinths increased in that manner, and thousands of *Liliums* raised from scales. We have not actually seen Narcissus bulbs similarly treated, though the plan may be resorted to by experts in increasing choice and valuable varieties. In ordinary culture Narcissus bulbs are taken up every second or third year for the removal of natural offsets, this being considered better than removing the small offsets yearly.

An example of slicing and its results may be seen in the small illustration (fig. 88), but inner circles of bulblets often form, and still more when transverse cuts are also made across the base of large bulbs.

Zonal Pelargoniums to Flower in August (N. S. P.).—The plants in 5-inch pots would be the better by a shift into a larger size, affording room for a little fresh soil being pressed down all round the ball of roots. The points of the shoots may be pinched once if you wish to induce a bushy habit; but as you require cut bloom, the stronger the growths the better will be the trusses and pips, therefore you must exercise judgment in these respects. The cold frame will be much the best place for the plants, as they can be encouraged to make growth, and when coming into flower the lights will be necessary to preserve the bloom; but up to that time ventilate freely, or even remove the lights during favourable weather to induce a sturdy habit. On choosing a number of trusses timed for expansion at a certain date, top the shoots at the same joint, or do not allow more than one leaf beyond each truss. The finest trusses we have seen had no growth beyond them. As the flowers expand fully seal their petals with a drop of gum, so that all you desire may be retained in good condition for travelling. Some exhibitors thin-out some of the buds with Grape scissors for securing fine bold individual flowers, larger than Mr. Cannell's watch, and it is not a small one. All the buds chosen should not be at exactly the same stage, or they may develop a little too quickly or slowly, according to the weather. Aim at having a number of grand trusses to choose from when the show day arrives.

Sundry Plants (J. C. S.).—Cycadaceous plants are closely allied to Conifers, but *Cycas revoluta* and some other species are Palm-like in aspect, and when well grown decidedly ornamental. *C. revoluta*, a native of China and Japan, produces a beautiful arching crown of deeply cut pinnate leaves of stout texture from a short stem. In the course of years the stem elongates, but plants are not often seen in pots or tubs with clear stems more than 3 or 4 feet long. The majority are much shorter, but the plants not less ornamental. They succeed in greenhouses, but the warmer these are the quicker the growth. Soil, turfy loam made porous with sand and broken charcoal pressed down firmly, is suitable. *Elaeodendron orientale* is probably the correct name of the next plant you mention, and usually grown as *Aralia Chabrieri*, not in greenhouses, which are usually too cold in winter, but in stoves. The plant has narrow, arching, deep green leaves, is very ornamental, and grows in a mixture of peat, loam, and sand. *Ipomœa Horsfalliae*, a beautiful crimson-flowered twining plant, is a native of the East Indies, and can only be grown satisfactorily in a temperature of 70° to 85° in summer, and 60° to 65° in winter; indeed the more heat it has the better it appears to thrive. The small leafy sprays of *Magnolia* are probably *M. stellata*, syn. *M. Halleri*; but a flowering spray is necessary for positive identification.

Asters for Exhibition (A. S.).—Some of the best Asters we have seen were grown in trenches prepared as if for Celery. The buds were thinned, but not necessarily to one on each plant, as a second bud not infrequently produced a better bloom at a given date. It is most important to keep the plants free from insects by occasional dustings with tobacco powder before the florets show colour. The blooms often need protection from hot sun and drenching rains. Clear soot water and manurial mulchings are good for Asters.

Chrysanthemum Leaves Diseased (J. S.).—The leaves are diseased sure enough, but not by the rust fungus (*Uredo chrysanthemi*). Instead of that they are infested by eelworm (*Tylenchus devastatrix*), the pest living in the tissues, and causing them to become brown or black and clammy on the upper surface. The animals usually attack the stem at or about the ground level, and the plants so attacked usually go off "without cause" when 2 feet or more or less in height, this usually occurring from the middle of May to a similar time in July. The pests are generally introduced in the potting material. There is no remedy for seriously infested plants. If taken early we have found dusting with quicklime slaked with a solution of sulphate of copper, 4 ozs. to a gallon of water, using sufficient of this and no more to cause the lime to fall into an apparently dry flower. Dust this on both sides of the leaves, not using an excessive coating, but just a thin film. It appears to sink into the tissues, and have a beneficial effect in arresting the progress of the ruinous invader.

Peach Shoots Injured—Carnation "Sport" (Bryn).—We cannot find anything in the shoots of a foreign organic nature, yet the tissues appear injured by something, and some of the parts are dead. This may have arisen partly from the dressing to which you allude, but mainly from the unripe condition of the wood. It is very weak, long-jointed, and immature, hence more likely to be injured by the substance applied by means of a sponge, and much stronger than was safe under the circumstances. We can only advise cutting away the injured parts, keeping the growths clean through the summer, and in the autumn carefully lifting the tree and relaying the roots in fresh compost. The border must be in a bad condition to give such indifferent growth. It is not the result of too little, but more likely of too much moisture, and possibly sour soil. It is impossible to say whether the name of your Carnation is correct or not. Its distinctness, or otherwise, can only be determined by actual comparison with others similar in character at an exhibition of these flowers, or in a large collection. The flower has been seen by three experts, each of whom suggested a different name, and none of these the one you mention. It is not the least uncommon for exactly the same sports of different kinds of flowers to occur in sundry places and during the same year.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (R. D.).—1, *Lælia purpurata*; 2, *L. elegans*; 3, *Cypripedium Rothschildianum*, poor form. (J. L. C.).—1, *Adiantum cuneatum grandiceps*; 2, *Asplenium bulbiferum*; 3, *Nephrolepis davallioides*; 4, *Lastrea filix-mas*; 5, *Athyrium filix-femina*; 6, *Pteris serrulata cristata*. (J. C. S.).—*Magnolia stellata* syn. *Halleana*. (M. B. W.).—1, *Amelanchier botryapium*; 2, *Spiræa prunifolia flore-pleno*; 3, *Chieranthus alpinus*; 4, *Corydalis lutea*; 5, *Lycium europæum*; 6, *Heuchera sanguinea*. (W. C. S.).—1, perhaps *Zephyranthes rosea*, specimen crushed; 2, *Pyrus japonica*; 3, *Saxifraga trifurcata*.

THE VALUE OF FARMYARD MANURE.

MUCH has been written and said during the last year or two to induce farmers to believe that the muck which has been looked upon by so many and for so long as their sheet anchor of fertility is of little or no practical value; nay, more, that in some cases and under some conditions it may do absolute harm. So when we consider the amount of labour bestowed upon the operations of filling, carting, and spreading manure, it seems to us an absolute necessity that we should carefully examine the evidence upon which it is being condemned, and not arrive at a rash conclusion on inconclusive data. At any rate, farmyard manure will continue to be made, whether it be valueless or not, and it will have to be made the best of, such as it is.

There seems to be no denying the fact that muck contains very valuable constituents, and as regards the least valuable of these, potash and phosphoric acid, the farmer gets nearly their full value if he gets the manure put quickly on to the land without having allowed the goodness to be washed out by rain in the yard. The same rule applies to the ammonia, which is its most valuable constituent, but in this case there is a further and greater cause of loss, and it is this that we propose to consider.

It will be remembered by old-time farmers that, thirty or forty years ago, when artificial manures were much less used than they are now, and on many a farm not an ounce was used at all, great care was taken of and much labour spent upon the dunghheap. During frosty weather in winter quantities of dung would be carted into hill in the fields; this would be required, as a rule, for the Turnip crop in June, but it would not remain quiet and undisturbed until that time; some time during the spring it would be all thoroughly turned over, every forkful would be moved. We can well remember asking the reason for this turning, and being told that the muck was better for it. No specific reason was given, and it was not until long afterwards we found that what we had

imagined was but a mechanical advantage was really a saving of nitrogen by the checking of the denitrifying action of the manure by turning. The old-time farmer knew that turning preserved the goodness of his manure, though he could not explain the reason, and he would turn his manure up in the yards in spring whether he required it for Turnips, or later on, for his Wheat.

The German chemists, Wagner and Maercker, have been conducting several series of very exhaustive experiments with the object of ascertaining the value of dung in practice. They have grown plants in large pots and applied to some of them artificial nitrogenous manures such as nitrate of soda and sulphate of ammonia, but no dung; to others they have applied dung in addition to the artificials. The results are remarkable, the nitrogen recovered in the crop being in every case less where dung was used, so that it would appear to do absolute harm. Here are the results:—

NITROGEN RECOVERED FOR EACH 100 APPLIED.

I.—WAGNER.

Manures alone.		Same Manures with Horsedung.	
Nitrate of soda	77	52	
Sulphate of ammonia	69	50	
Cattle urine	69	40	
Pasture grass	43	20	

II.—MAERCKER.

Manures alone.		Same Manures with Farmyard Manure.	
Nitrate of soda	55	35	
Sulphate of ammonia	37	31	
Cow urine	29	22	

Taken alone, Wagner's and Maercker's experiments would seem conclusive enough. On the other hand, however, Pagnoul, a French chemist, growing Mustard and grass in very large pots, tried the effect of dung upon dressings of artificial nitrogen, and found not only that the dunged pots grew no less than those with nitrate of soda only, but there was an increase due to the dung alone, so that in his trials denitrification does not seem to have taken place to any serious extent. But there was one great difference between his and the German trials, and that was in the proportion of manure to soil used, for whereas in the German 7 per cent. of manure, representing about 70 tons per acre, was used, in the French trials only 2 per cent., or twenty loads, of manure per acre was applied. This seems to suggest that there is a limit to the quantity of dung that can be profitably applied to land, and few farmers would be found who would even hint at contradicting such a conclusion.

But if reasonable quantities of manure used in pot culture can be shown to do good rather than harm, can any evidence be adduced to show that in field experiments carefully conducted the same result will be obtained? Of course field trials are apt to vary very much, but in the experiments in the growth of roots at Rothamsted, taking the average results of a series of years, we find that from mixtures of farmyard manure and artificials better and more enduring results have been obtained than from artificials alone.

Valuable as pot experiments may be, we think that we should read a little between the lines in drawing conclusions from them, for an ounce of practice is worth a pound of theory; and we want to know how best to grow crops in fields, not in pots. We all know that many plants would refuse to grow in too rich a soil, for under such conditions there is always a lack of root power. The plant that is, as it were, born with a silver spoon in its mouth, finding ample supplies of food ready at hand, does not make the root that a plant does which in poor soil has to go abroad for a living. Very little upsets the equilibrium of the pampered child of luxury, so we must not attach too much importance to trials conducted in soil containing manure at the rate of 70 tons per acre.

The fact that nitrification must take place before manures are available as plant food still remains, and the conclusions we draw are that this process had better take place in the manure hill than in the land, for in the hill nothing can be set free in the process that is not

contained in the heap, and if well turned over at a suitable time we think the loss of ammonia even here would not be great; but in the land the manure, if the German experiments are worth anything, may set free more nitrogen than it does itself contain, and therefore the land may be so much the poorer by its application, except for the small quantities of phosphate of lime and potash which it also contains.

How, then, must we use our yard muck? We must turn it well before using. If intended to be used in conjunction with nitrate of soda or sulphate of ammonia the muck must be put on some time before the artificials, and too much must not be used at one dressing; few, we think, will err in this direction as regards field culture.

WORK ON THE HOME FARM.

The weather is drier, but still very cold, and the sun seldom breaks through the clouds. The general result of the week is not hopeful. Spring corn does not grow at all, and Wheats, though still looking well, are showing signs of the attacks of rust. Weeds do not forget to make headway, and all hands are required for the hoeing, and this year Barley and Oats really need hoeing; the corn grows badly, and so gives opportunity for the weeds. Fortunate is it where Clover seeds have not been sown early, for harrowing is very beneficial this season; it not only destroys weeds, but loosens the surface soil, which has become very solid, owing to the heavy rains.

We are giving a final stirring to the Swede land; a good dragging and harrowing, and the gathering off of any little bits of twitch, will leave the land ready for ridging up and drilling. As we find Swedes quite easy to grow without muck we shall save the labour of applying it now, and reserve it for next year's Wheat or Potatoes. Bonemeal and superphosphate will, however, be very liberally given, say 7 cwt. per acre in mixture, and we shall have no doubt about securing a crop.

Pastures keep good, but stock sells badly. We have clipped our hoggets, sold some, and turned the rest among the cattle on grass. They will put on more flesh, and the markets can hardly be much worse. Fat ewes, weighing 160 lbs. carcase weight, have sold for as little as 40s., or only 3d. per lb., but the consumer will not eat solid fat, and we do not blame him for it. In fact, a nice hoggett of about 64 or 68 lbs. will fetch about the same price. It was remarked the other day at a local market that 40s. seemed to be the price of a sheep, no matter what the weight might be, and as a fact 8s. would quite cover the extremes of price.

We are still earthing our Potatoes over for fear of frost, but some are coming through the second time. They must take their chance now. Mangold have come well, and so have the weeds. The latter must be hoed out as soon as the Mangold can be clearly seen, or they will soon smother the young plants.

Cattle are doing well, and do not seem to feel the cold weather much. They have plenty to eat, which is a blessing.

Work being forward labour is plentiful, and several men are out of work.

We have washed the ewes, so trust to have warm weather for clipping next week.

REMARKS.

22nd.—Dull early, rain at 11.15 A.M., generally sunny after.
 23rd.—An almost perfect day. Cloudy evening and rain at night.
 24th.—Generally sunny, but hazy, and at times cloudy and almost threatening.
 25th.—Overcast all day, with a gleam of sun at noon.
 26th.—Overcast morning with one or two gleams of sun; faint sun generally from noon.
 27th.—Overcast and dull early, frequent faint sun from 11 A.M. to 2 P.M.; dark and threatening, with spots of rain from about 3.30 P.M. to 4.30 P.M.
 28th.—Rainy from midnight to 4 A.M., overcast morning; fine afternoon, sunny at times.
 Rather dull. Rain still small. Temperature near the average.—G. J. SYMONS.

W. CLIBRAN & SON'S DESCRIPTIVE CATALOGUE OF Garden & Conservatory Plants.

Replete with invaluable information, is sent post free to any address on application. Buyers are invited to inspect the magnificent representative collections of every class of these plants at the **OLDFIELD NURSERIES, ALTRINCHAM**. To those who cannot come the fullest information as to price, sizes, &c., will be sent on request.

HERBACEOUS, ALPINE, AQUATIC, AND BOG PLANTS.

Of these alone the stock numbers several hundred thousand plants, all of the very best procurable types.

COLLECTIONS (our Selection only):—12 sorts for hot dry situations on Rockery, Walls, &c., 4/-; 12 for moist shady Rockeries, 4/-; 12 for sunny borders, 4/- and 6/-; 6 Aquatic plants for deep water, 6/-; 12 Aquatics for boggy places, 4/- and 6/-; Asters (Michaelmas Daisies), 6 sorts for 2/6, 12 for 4/-, 25 for 7/6; Sempervivums, 12 sorts from 3/6; 50 fine showy Border perennials in 50 varieties, 15/- and 21/-; 100 ditto, in 100 varieties, 35/- and 42/-. As all these plants are supplied in pots, they may be planted out practically at any time.

HARDY CLIMBERS FOR OUTDOORS.

(Our Selection.) Clematis, 12 fine sorts from 10/6; Ivies (finest green and variegated varieties), Honeysuckles, Wistarias, self-clinging and other Virginian Creepers, Ceanothus, Menispermum, Aristolochia, 12 fine sorts in pots, 12/-.

CLIMBERS FOR GREENHOUSE AND CONSERVATORY,

Including Passion Flowers in great variety. Stephanotis (the freest blooming form), Clerodendron Balfouri, Lapageria (finest varieties), and many others at 10/- and 30/- per dozen and upwards, according to size.

STOVE AND GREENHOUSE PLANTS, FERNS, &c.

12 varieties flowering Stove Plants from 10/-; 12 varieties foliage Stove Plants from 18/-; 12 varieties Greenhouse Plants from 12/6; 12 varieties Caladiums from 12/-; 12 varieties Crotons from 24/-; 6 Epiphyllums from 7/6; 12 distinct named Gloxinias from 18/-; 12 Streptocarpus seedlings, in 3 inch pots, from 6/-; 12 double seedling Begonias, finest selected, true to colour and shade, 12/- to 30/-; 12 distinct Ferns for stove from 9/-; 12 ditto for Greenhouse from 6/-; 12 different Adiantums from 6/-; seedling Ferns for Rockeries, Table Decoration, &c., from 3/- per dozen.

DOUBLE CACTUS DAHLIAS.

SPECIAL OFFER.—12 splendid Cactus Dahlias, including the following superb Novelties of 1897:—Cycle, Ensign, Flossie, Harry Stredwick, and Mrs. Kingsley Foster, together with Beatrice, George Marlow, J. E. Frewer, Lady Penzance, Mrs. Wilson Noble, Mrs. Francis Fell, and Viscount Boyne. Post free, 12/6.

Clibrans, Altrincham & Manchester

NATIVE GUANO

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price £3 10/- per Ton in Bags.

Lots under 10 cwt., 4/- per cwt. One cwt. Sample Bag sent car. paid to any station in England on receipt of P.O. for 5/-.

Extracts from 22nd Annual Collection of Reports:—

NATIVE GUANO for POTATOES, VEGETABLES, &c.—G. HEFFORD, Worcester: "Used for Potatoes and all Vegetables; answered well for all. A very valuable article indeed; a great check to slugs." J. GABRIEL, Long Eaton: "Used for Onions, Peas, Celery, and Tomatoes: never had better results from any manure; growth quick, good quality."

NATIVE GUANO for FRUIT, ROSES, TOMATOES, &c.—E. COX, Fawley Gardens, Daventry: "Used for Grapes, Peaches, Nectarines, and all garden fruits; results, all very satisfactory; a very good manure." G. CLINGING, Gardener, Haywards Heath: "Used for Lawns and Tomatoes; results, excellent; Lawns a beautiful dark green colour."

Orders to the **NATIVE GUANO CO., Ltd.**, 29, New Bridge Street, Blackfriars, London, where Pamphlets of Testimonials, &c., may be obtained. **AGENTS WANTED.**

No. 937.—VOL. XXXVI., THIRD SERIES.

CARNATIONS!

Mr. WEGUELIN'S CATALOGUE for 1898 comprises the Latest Novelties & Choicest Exhibition Varieties in cultivation. Sent Gratis on application to—

H. W. WEGUELIN, F.R.H.S.,
ST. MARY CHURCH, TORQUAY.

LONDON FERN NURSERIES,

LOUGHBOROUGH JUNCTION, LONDON, S.W.—Ferns, large and small, in variety; Aralias, Grevilleas, Cyperus, Ficus, Ericas, Palms, Dracenas, Aspidistras, Hydrangeas, Pelargoniums, Fuchsias, Marguerites, Crotons, &c. Trade, send for Wholesale List. Special List for Amateurs, send for one.—J. E. SMITH.

BEGONIAS.

B. R. DAVIS' Gold Medal Strain.

The LARGEST and MOST SUPERB COLLECTION in the World, of DOUBLE and SINGLE TUBEROUS-ROOTED. See CATALOGUE and GUIDE BOOK FREE.

B. R. DAVIS, Begonia Specialist, &c.,
Yeovil Nurseries, SOMERSET.

100,000 VEITCH'S AUTUMN GIANT

Cauliflower, 3/6 per 1000; Early London, 3/6; Late Italian, 4/-; Knight's Protecting Spring Broccoli, 3/6; Edmond's Superb, 5/-; Drumhead Savoy, Myatt's Cabbage, and Dalkeith Brussels Sprout, all 2/6; Drumhead Cattle Cabbage, 2/-.—W. HORNE, Cliffe, Rochester, Kent.

ORCHIDS! ORCHIDS!!—10,000 MUST GO.

This being the end of the importing season I must clear off my surplus stock regardless of cost. I have therefore decided to make the following unprecedented offer: 6 assorted Orchids, 6/-; 12, 10/-; 25, 20/-; 50, 35/-; 100, 60/-. Every plant guaranteed sound and true to name.—J. W. MOORE, Orchid Importer, Rawdon, near Leeds.

NOTICE.—Don't stake your Carnations till you

have seen the Patent Improved Coil Stake. No tying required; stakes last a lifetime. The greatest boon ever offered to growers. Only wants seeing. 7/6 per 100; sample dozen, 1/-, carriage paid. Cash with order.—A. PORTER, Stone House, Maidstone.

DEFY THE BIRDS by Buying our Noted

ROTLESS TANNED NETTING, as supplied to the Principal Gardeners in the Kingdom. Orders over 5/- value are sent Carriage Paid. 100 yds. by 1 yd., 3/-; 200 yds. by 1 yd., 6/-; 300 yds. by 1 yd., 9/-. Can supply any length and width.—UNIVERSAL SUPPLY ASSOCIATION, East Street Works, Reading. (Name Paper.)

GREENHOUSE SALE, Half-price (off season),

7 by 5, 28/6, 38/6; 10 by 6, 42/-, 50/-; 14 by 6, 52/6, 65/-; 10 by 8, 52/6, 58/6; 14 by 10, 75/-, 88/6; 20 by 10, 87/6, £5 15/-. FRAMES, 8/9, 14/6, 22/6. FOWL HOUSES, 8/9, 10/9, 14/6. Approval.—HYPOLITE, DEPTFORD.

HEATING APPARATUS.—Medals 1875 and

1881. Catalogue of Boilers, Pipes, and Fittings free. W. Jones' Treatise, "Heating by Hot Water," second edition, 216 pages, 2/6; post free, 2/10.—JONES and ATTWOOD, Stourbridge.

PURE WOOD CHARCOAL, Specially Prepared

for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—**HIRST, BROOKE & HIRST, Ltd., Leeds.**

VERMOREL'S KNAPSACK PUMPS

For Spraying Fruit Trees & Root Crops.
390 FIRST PRIZES AND MEDALS.

"ECLAIR" Spraying Pump .. 35/-

"TORPILLE" Powdering Pump 30/-

"VERMOREL" (Eclair Bouillie).
The Best Spraying Mixture for instantaneous use.

Sole Agents—**CHARLES CLARK & CO.,**
20, Great St. Helens, London, E.C.

THE "SPROUGHTON" HOE.

Simpler than the Dutch Hoe and much superior. The most perfect Duplex (Push and Draw) Hoe yet made. Highly approved at Chiswick (R.H.S.), and at the Royal Gardens, Windsor. Strongly commended by Sutton & Sons, Mr. E. Molynex, and other leading horticulturists. Copies of testimonials from Rev. A. FOSTER-MELLIAR, Sproughton, Ipswich. Price 1/10 each. Of all Ironmongers, or of **Messrs. RANSOMES, SIMS & JEFFRIES,** PRINCES STREET, IPSWICH.

Journal of Horticulture.

THURSDAY, JUNE 9, 1898.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St. London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

FALLACIES ABOUT SOILS.

IT seems natural that in connection with any calling there should spring up certain practices originally based upon sound principles, and which under some circumstances produced the best possible results. The success of any individual in the conduct of business worked by skilled labour, or in the culture of any plant or crop, is invariably followed by hosts of imitators, who seem to think it only necessary to imitate exactly to insure similar success. Yet as no two cases are exactly alike in all the surrounding circumstances, it so happens that a stereotyped following of old methods does not produce the great desideratum of modern times—viz., the best possible result with the least expenditure of time or money.

In applying the foregoing remarks to matters relative to horticulture, it seems to me that we have too long bound ourselves, as it were, to regulation mixtures in the matter of composts for pot plants. One of the many things which puzzled me greatly when I first began to work in a garden, was the mysterious and complicated mixtures employed for various kinds of plants. I argued the matter with myself in this way—In outdoor gardening, if we have a good loamy soil, and keep up its fertility by means of the necessary manuring, plants of infinitely different character succeed in it. Look, for instance, at the great variety of plants now employed for bedding purposes; while they are growing in pots in the houses, many persons seem to think it absolutely necessary to have good fibrous loam to grow some of them in, or peat and numerous different ingredients for others. As soon, however, as the bedding season arrives they are planted, and all share alike in the matter of soil; and it may, I think, be safely asserted that, given favourable weather and proper attention, all classes of bedding plants thrive better during their stay in the open air than while growing in pots in specially prepared soil. Here then, I think, is a wide field of thought for our reflective faculties to ponder upon.

During recent years many men have apparently considered the matter, and launched out into startling methods of procedure as a result of their

No. 2593.—VOL. XCVIII., OLD SERIES.

deductions, for it is not so common a practice now as formerly to consider expensively made Vine borders necessary for the production of good Grapes, or the complicated composts of the faddist for the growth of superior plants. The market growers who, through the keen competition of modern times, have found it necessary to make every shilling go as far as possible, soon found out that their working expenses could be enormously reduced by using simple soils well stored with fertility, in preference to mixtures at one time thought essential, and which were pedantically termed "properly proportioned combinations of the elements necessary for the support of plant life." A plentiful supply of good turfy loam may be essential for the successful cultivation of many plants in pots, but I have proved conclusively that quite as good results may be obtained without it in growing the majority of softwooded kinds. Its great value lies in the fact that, as the fibre decays slowly, it gives up its elements of fertility by degrees, and is, in consequence, not quickly exhausted, and also prevents the compost becoming pasty and sour after the first year. In bygone days, when gigantic plants were more generally grown than they are at the present time, fibrous loam and peat were almost exclusively used for pot plants, doubtless because observant cultivators and successful exhibitors found that large specimens could be kept in health and vigour for a long time by using only soil of that description, hence it became the practice to use such for small as well as large plants.

When any particular practice is pursued by a successful cultivator, there is generally no lack of others ready to follow, I might say blindly, the same course, notwithstanding the fact that it may not be the most suitable one in all, or even the majority of instances. Turfy loam is really not required for plants which are kept in the same pots for a year or so, and then shaken out and repotted. I will even go farther, and say that many softwooded plants, such as Pelargoniums, Fuchsias, and Marguerites, which are intended for flowering in 5 and 6-inch pots, will grow more quickly, and prove quite as satisfactory in other respects, if good garden soil is used to pot them in. There is naturally a great difference in the texture of soils in various localities, and in preparing them for potting purposes they must be treated according to their condition. Let us take, for example, a rather strong, or, to put the matter more plainly, stiff loam. If a little lime rubble or wood ashes is added to it, as well as some partially decayed manure, it is brought into the right mechanical condition, and is rich enough to grow almost any softwooded plant well. Such a compost should be fairly dry at the time it is used for potting, and will not need pressing quite so firmly as when a lighter soil is used. A good waterer will also observe that until the roots of a plant have thoroughly permeated such a compost, watering must be done sparingly; but this is an advantage, as the less water a plant requires to keep it healthy and vigorous, the greater is the saving of labour effected.

Now let us consider the case of a good loamy garden or field soil, neither too heavy on the one hand, nor too light on the other. Such is admirably adapted for the growth of plants in pots, and often needs but little addition. In districts where such soil abounds it is often slightly deficient in lime. It is therefore obvious that a quart of lime to a barrowload of soil will make it richer in plant food. Such soils, when taken from land which has been freely manured for years, often do not need any other addition, as when the plants need stimulating food such can easily be given in the form of liquid or chemical manures. Again, in some instances the soil of the district is somewhat light, not poor, except in the sense that in dry seasons it does not retain moisture well. A load of clay kept in a shed, and pounded to powder when dry, if mixed with ten or fifteen loads of the light soil above described, will make it quite suitable for the growth of plants in pots if a little chemical manure is added; and such a compost is far cheaper than obtaining turfy loam from a distance, and, moreover, answers the purpose equally well. These are matters of vital importance in connection with commercial horticulture, as the man who can make the best use of the materials at command may often conduct business in a profitable way when others, under similar circumstances, fail, through following too closely the "beaten track."

Tomato growing has now become quite a national industry, and although under favourable conditions it is one of the most easily grown plants, yet we hear perhaps more complaints about attacks of disease, and partial failures, than in connection with any other indoor crop; but I am bold to say that there are two causes which contribute more than all others to want of success in Tomato culture; these are insufficient ventilation, and omission to plant in sweet fresh soil. The idea that the "Love Apple" requires good turfy loam to grow it to perfection is quite a fallacy. Any fresh garden soil not too rich will answer the purpose quite as well as the most complicated mixture formed by dabblers in the science of chemistry. Good growth, not too strong, is then secured, and when a fair quantity of fruit is set it is an easy matter to feed as much as is necessary with natural liquid and chemical manures. What Tomatoes abhor is to be planted year after year in the same soil; it is then only a question of time before they begin to show signs of disease or refuse to grow altogether. "Yes," but some growers on a large scale will say, "but how are we to constantly provide fresh soil for them?" The matter is simple enough where practicable—namely, secure a field near your Tomato houses, and each year remove the top spit of soil from the Tomato borders, replace it with a thickness of 8 inches from the field, and fill up the hollows thus made with the soil from the Tomato houses. The land will then continue to grow good crops of vegetables, and serious Tomato troubles will practically cease. Some cultivators might urge that such a proceeding would not pay, but as it pays to do it on a small scale, I am quite certain it may be made remunerative on a large one. Enormous sums of money have before now been wasted in carting turfy loam from a distance for Tomato growing, when plenty—which would have answered the purpose equally well—could have been obtained a few yards from where required.

The horticulture of the future must inevitably be conducted on strictly economical lines, and in the matter of soils for pot plants, Vines, and Tomatoes there is plenty of room for practising a more rigid economy. I have sufficient faith in what I write to practise it myself, and have this season planted 2000 Tomatoes in ordinary garden soil, rather lighter than I should prefer. The results promise to be a great success in every way, as heavy crops are swelling fast, and in the early houses the fruit is beginning to colour.—H. D., Leicester.

[Perhaps our able correspondent knows, though he does not say, that the interchange of soil advocated is the established practice of the most extensive growers of Cucumbers, Tomatoes, and various kinds of market plants in the kingdom; while in the production of Grapes by the ton the clever producers simply make the best of the natural soil of the site and immediate surroundings of their operations, whether the predominating factor be clay or sand. The results would astonish numbers of gardeners who have not seen them, and are altogether gratifying and encouraging.]

FLOWERS OF THE SEASON.

WITH the garden full of flowers, of dazzling or of softest gentlest beauty, it seems hard to leave it, even to take pen in hand to tell of its charms. More pleasant is it to sit or work among the flowers, delighting the while in the garden's sights and sounds. When Tulips open their cups, to be filled with the radiant sunlight; when Alyssums shine, resplendent with its glow; when hosts of flowers of all colours, with their tints brightened by its magic power, meet the eye, it requires an effort to tear ourselves from them, to put pen and ink to paper, to strive to give even a feeble idea of the beauty of the time. From the sky, dappled with fleecy clouds, none large enough or dense enough to obscure the glory of the sun, to the meanest flower which carpets the earth, all Nature seems glorified by the spirit of the season. The mountain side is green with young verdure, the belts of forest near its base vivid as at no other time. Where the streams fall over its grey rock faces, they shine like polished silver. The meadows are exquisitely green, save where spangled with Daisies or Buttercups. The young Oats have covered the fields, so short a time ago brown or black with bare earth. The very air is alive with the energy of the time. Butterfly and bee—nay, insect life of all kinds abounds, and their hum, as they fly, mingles with the song of birds.

The life of the Daffodils is nearly over for the year; their time of rest is at hand. Though we shall miss them we cannot be forlorn with the glory of the Tulips before our eyes. Very beautiful are they,

and none is of more value than some of the old cottage garden varieties which have survived years of neglect, and which need less care than many more sought after. Very showy and very beautiful as well is the old Tulip Golden Crown in its early flowering stage before the red which just margins its segments spreads until it flushes over almost all the flower. Less pointed in shape, but very beautiful, is the one named Golden Eagle, with its large self-coloured yellow flowers. Very effective is York and Lancaster, which at first is yellow and red, but afterwards passes to creamy white with large deep red blotches. Then there is Sunset, a rich coloured red and yellow Tulip, whose tints are sufficiently well indicated by the name it bears. All of these are good hardy sorts likely to give satisfaction in many gardens where the more formal if very beautiful English Tulips are not much cared for.

There are many beautiful plants among the Ranunculi, even if we leave out of our reckoning those which in past days were so popular as florists' flowers. "Past days," one says advisedly, for the florists' Ranunculus has fallen upon evil times, and the coarse flowers which pass muster at the present time would have caused pain to the old growers of fifty years ago. It is not of these, however, that one would like to speak at present, but of an old favourite of the hardy flower grower—*Ranunculus bulbosus* fl.-pl. Very beautiful are its imbricated double flowers of the finest gold, shining with a lustre as if burnished. Not fastidious as to soil, although preferring a moist one, and thriving well here on the boggy margin of a pool is this double Cuckoo Bud or Gold Cup. It is only about 6 or 8 inches high, and gives no trouble to grow.

Recently, on page 402, the Canadian *Viola canadensis* was briefly mentioned. Now another Violet presents itself—not needlessly, because there are many of the race which have, in the florist's hand, almost driven such species as these to be grown only by a few. The one now under notice is *Viola cucullata*, another North American species, and one which has been introduced for more than 130 years. We generally associate the Violet with fragrance, but as there is hardly a rule without an exception, sweet odours are not always possessed by these flowers. Of the scentless species, *V. cucullata* is one, and its claims upon us rest in its pretty violet-blue, purple, or striped flowers. The form grown in my garden is the last of these, and it pleases nearly all by its combination of white and deep violet-blue striped blooms. It did not flower for a year or two after being planted in its present position by a stone edging at the base of a rockery with an east exposure, but it has flowered annually and freely since that time. Its rather cordate leaves are dark green, and the flowers are produced on good stalks, besides being of fair size. The Hooded Violet possesses several varieties, one of which was figured in Maund's "Botanic Garden" as *V. palmensis*.

A glance at the garden shows us golden and orange Trolliuses, the golden Spanish Whin—*Genista hispanica*; the crimson and gold *Cytisus scoparius* Andreanus; the beautiful little *Cytisus Ardoini*, and others of kindred race. The tasselled Lilacs are in bloom, though may be over in the earlier South; and the Laburnums will soon be showers of gold. *Pyrus Maulei* has not yet lost its scarlet flowers, while the buds of the crimson Roses begin to show through their green envelopment. The orange cylinders of *Calampelis scabra* have begun to brighten the trellis on the outhouse gable; there is colour in the buds of *Lathyrus pubescens* by its side. Honeysuckle is budded, and the May blossom is bright with its fragrant blooms. The rock-garden and borders are gay with Sun Roses, Candytufts, Saxifrages, Aubrietias, Alyssums, Lychnises, Spanish Squills, Honesty, and many more, while Columbines hang their pretty flowers from the tops of their long stalks, and wave as the wind goes by. Irises grow plentiful, too, and Pinks are in bud, telling us of other pleasures yet to come.—S. ARNOTT.

ODONTOGLOSSUM ANDRIANÆ VENUSTUM.

VISITORS to the recent Temple Show will remember with delight the beautiful group of *Odontoglossums* sent from Belgium by Mons. L. Linden, and those of them who could get close enough would see and admire the handsome *Odontoglossum venustum*, which is depicted in the engraving (fig. 89). One flower only is shown from the long spike, and it can readily be seen how finely this *Odontoglossum* is marked. The ground colour of the flower is cream, but this was almost obscured by the bright brown spots, which spread in the greatest profusion over the upper sepal, petals, and lip. On the lower sepals the same colour took the form of bars and blotches on a cream base. It was

very much admired, and the members of the Orchid Committee expressed their appreciation by assigning to it a first-class certificate.

THUNIA MARSHALLIANA.

THE earliest flowers of this pretty species are now open, much earlier than usual. The plants carrying the flowers are about 15 inches high, have been grown in the full sun in pots about 5 inches across. Though various reasons have been assigned for *Thunias* not flowering, there is not the least doubt that the most frequent fault is growing them in hot, moist, and shady houses, and not taking sufficient care that the stems are well ripened in autumn.

It is our practice, after the flowers are past, to gradually dry the plants, and during the greater part of the summer they are kept out

FIG. 89.—ODONTOGLOSSUM ANDRIANÆ VENUSTUM.

of doors in the full sun. Sometimes they get quite blackened, and are to all appearances dead, but the more thoroughly they are baked in summer the better they flower the next season. It is a mistake, too, to allow the temperature in winter to drop unduly, and anything below 50° is bad for the plants. The stems may be all shaken quite clear of the compost, and tied in bundles of a dozen or more, these being suspended from the roof, or placed in any out of the way corner of a warm house, so that no great amount of room is taken up.

As soon as signs of growth are apparent at the base of the stems, they should be potted in equal parts of peat fibre, loam, and chopped sphagnum moss. Drain the pots carefully, and plant so that the base of the old stem just rests on the top of the compost, this latter being finished below the rim rather than above it. A neat stake should be placed to each stem, and the plants removed to their growing quarters, which cannot be too much exposed to the sun, and must be hot and moist.

When first potted little moisture is needed, as there are no roots to take it up, but directly the latter begin to run about the compost the supply must be sensibly increased. The blossoms occur on drooping spikes at the apex of growth, and are pure white with a yellow lip, this being covered with long shaggy hairs. When the flowers are partly expanded take the plants to a drier rather cooler house, the least damp settling on them being fatal to their beauty, and leading to spotting and disfigurement. It is a widely distributed plant in the Dendrobium region about Moulmein and Lower Burmah, plentiful enough to be always cheap.—H. R. R.

ORCHIDS ROUND LONDON.

ROSEFIELD—SEVENOAKS.

NOT many months ago—in fact early in the new year—the Rosefield collection of Orchids was visited, and a few jottings found a place in the Journal. Then, however, the state of affairs was vastly different from now, for with few exceptions plants only were seen, whereas on the occasion of the present visit there was a wealth of flowers amongst the *Odontoglossums*. As was noted on the occasion of the previous visit to Sevenoaks, it is of *Odontoglossum crispum* that Mr. de Barri Crawshay makes a speciality, and he grows them well. There is no forest of glass, but simply a few houses for the accommodation of the plants the owner loves so much and knows so well. They are his pets, that he tends with loving care, visiting them late at night to try and insure the precious spikes being safe from slugs, which even then occasionally become the masters of the situation.

The collection of forms of *Odontoglossum crispum* is a very comprehensive one, and amongst the plants are observable some of more than average merit. The colours ranged from pure white to white with many and with few spots of the customary varying colour, while the form and substance of some are those of the ideal *crispum*. Mr. Crawshaw is, and rightly, a great stickler for good shape, and those that are defective in this respect are certain of severe criticism from him. Happily, too, he is as strongly condemnatory of faults in his own flowers as he is in those of others, and none that shows serious blemishes on first expanding at Rosefield is retained. Thus will the quality of the varieties be improved year by year, until a standard of the greatest possible excellence has been attained to. Laws have been laid down and are observed, and they apply not only to the points just adverted to, but also to the advisability of giving names to every one. This is not done, and very properly, and it would be advantageous if indiscriminate naming amongst other plants as well as Orchids could be checked.

The exigencies of space preclude descriptions being given of any of the excellent varieties seen, for there are other plants that require and deserve a line of comment now. As regards the culture of these Orchids, the chief aim is apparently to secure a hard strong growth, this being sought for, and found, in cleanliness of the leaves and pseudo-bulbs and in a cool airy atmosphere. The result is that the colour of the foliage is deep, and shining with health, and the foliage rattles when touched with the hand. By these means the plants produce fine spikes of flowers of considerable size, though in this respect, as well as in the colouration, they obviously vary considerably, according to their age.

Amongst the several other Orchids to be seen in the same creditable condition are *Cattleya Mendeli*, of which the stock, though small, is rich in promise. Speaking of this charming Orchid reminds of an experience in repotting that was experienced at Rosefield. A small plant was procured and potted in the ordinary way on arrival, but was twice knocked over and the pot smashed. Thus it had to have fresh compost three times before the first growth was complete, and the result is the new pseudo-bulb is longer than the old, while the leaves are much larger and stouter. This points to appreciation of good food, even though it be given through unorthodox channels. The varieties of *Vanda tricolor* are very fine, some of the rarer ones being noted amidst the healthy plants. These, which are all growing in the same house, are all in splendid condition, and this remark applies with equal force to young and old, large and small, and it proves conclusively that the air of this pretty Kentish town and the treatment they receive are entirely congenial.

Turning to the *Laelias*, evidence of the same excellence of culture is readily seen, and as these again are great favourites with their owner they receive goodly attention at his hands. Some of the plants are new, while others are old; one specimen of *L. purpurata* that has been at Rosefield for just over thirteen years was at the time of this visit just producing its first spike of flowers. Perhaps ere now it has gone, and will know Sevenoaks no more, for such would assuredly be its fate if it proved a bad variety. Let us hope that after possessing his soul in patience for thirteen years Mr. Crawshaw would be richly rewarded. Then, too, were noted *L. Amesiana*, of which the Rosefield variety is such a superb one; *Odontoglossum nævium majus*, *O. polyanthum*, *Maxillaria Sanderiana*, and, growing at the warmer end of the *Odontoglossum* house, some splendid specimens of *Masdevallia towarensis*. There are others that ought to be mentioned, but we must return to London, where there is still much to see.—H. J. WRIGHT.

GROWING DIPLADENIAS.

WHETHER grown into large trained specimens for exhibition or for the decoration of the stove, these lovely climbers must always hold a foremost position amongst our choicest stove plants. If not wanted for exhibition the best plan is to fasten a trellis of wires underneath the roof of the house and at 8 or 10 inches from it. Over this the plants should be allowed to ramble freely, taking care to keep the shoots evenly and thinly disposed, so as to allow plenty of room for the proper development of the leaves and perfect ripening of the wood, which is highly essential to the free production of their flowers. Grown in this way, with some of the dark highly coloured flowers produced by *Brearleyana* and hybrid side by side, or intermingled with the delicate rosy pink ones of *D. amœna*, they present one of the most charming sights imaginable. The flowers when gathered are very attractive arranged in shallow dishes with a few fronds of *Adiantum gracillimum* forming a sort of screen over them, and if gathered in the morning when the house is coolest they remain in good condition for several days.

Dipladenias are easily propagated by means of cuttings. These will root at any time of the year, but the best time is in the spring,

and the cuttings to be preferred are the young growths from the preceding year's wood, taken off with a heel when about 3 inches long. Inserted singly in 2½-inch pots, in a mixture of half peat and half sand, and placed under a bell-glass in the hottest part of the stove, these will form roots in about a fortnight, and then must be gradually exposed to the ordinary temperature of the house. Next to these I prefer cuttings made from strong half-ripened shoots, such as may be obtained in May or June, but by rooting them in the early part of the year they get fairly started before the hottest weather comes, and perfect their growth before the winter.

To grow them well—and if not well grown they are best left alone—they require a rather high temperature when in active growth, and even in the winter when at rest they must never be subjected to a lower temperature than 50° to 55°. If wanted to flower in May they must be started early in January, but generally speaking the beginning or middle of February is soon enough. At first starting they should be given a temperature of 60° to 65° at night, with a rise of 5° by day, gradually increasing it as the days lengthen, until by the end of April it ranges from 70° to 75° at night, and from 75° to 80° by day, allowing it to rise to 85° or even 90° with sun. They delight in a moist atmosphere, and must at all times be shaded from bright sunshine, admitting at the same time as much light as possible. For this purpose the house should be provided with blinds, so that they may be rolled up and the plants exposed to the full influence of the light on every occasion when there is no sun.

The compost for *Dipladenias* should consist of three parts brown fibrous peat to two parts loam, which must be as turfy as possible, and all fine soil removed from it by sifting; to this add one-quarter part each of sand and charcoal, the latter broken to the size of acorns. A small quantity of chemical manure may be added. If really good turfy loam is not available they may be potted in all peat; on no account should poor loam, destitute of fibre, be used. The pots must be well drained, and great care exercised in watering at all seasons, few plants being more liable to injury through neglect in this respect than *Dipladenias*. During the winter especially, and before they have fairly taken to the new soil after potting, water must be cautiously applied, allowing the soil to get thoroughly dry before watering, but not to such an extent as to cause them to flag. I have seen them treated as deciduous plants, and made to lose all their foliage in the winter by keeping them dry at the roots, but such treatment is decidedly wrong; they are naturally evergreen, and must at all times be given enough water to enable them to retain some of their leaves fresh and healthy.

Almost all kinds of insects to which stove plants are subject will live on *Dipladenias*, but with proper treatment the only ones whose attacks need be feared are mealy bug and brown scale, and these—provided the plants are thoroughly cleansed before they are started in the spring—can generally be kept pretty well in check by using the syringe freely mornings and afternoons. Should they become too firmly established to be kept under by these means, syringing with petroleum will get rid of most of them.

A wineglassful to 3 gallons of water is as much as it is consistent with safety to use, as when growing freely the young leaves are very tender and easily injured. Even this quantity must be carefully applied, mixing it well with the water before syringing it over the plants, and washing it off with clean water a few minutes afterwards. Keep them well shaded for two or three days, and if properly managed no evil will result from the application, which, if necessary, may be repeated in a week or ten days. Scale may be got rid of in the same way, but being more difficult to destroy it is generally necessary to syringe the plants three or four times in succession at intervals of not less than a week.

As soon as the flower buds appear give weak liquid manure at every alternate watering; that made from fresh cow or sheep manure and diluted with clear water to the requisite strength is as good as any for them. This will greatly prolong their season of blooming, besides making the individual flowers finer in every respect. Without some such aid the trusses produced after the first flowers open will be very weak, and will have only a small quantity of buds on each; strong trusses will frequently produce as many as thirty flowers in succession, lasting over a period of nearly two months.

Any plants that are intended for exhibition should be supplied with balloon or other shaped trellises of the size they are likely to require, and the whole of the wood fastened thereto before they are started. Each young shoot when about 3 inches in length should have a string placed for it to climb on, running from the trellis to the highest part of the roof, as before mentioned, giving each shoot a fair amount of room. Comparatively small pots should be used, those 14 or 15 inches in diameter being sufficiently large for even the finest specimens. In pots of this size they may be grown year after year, turning them out just as they start into growth, and removing enough of the old soil to permit their being placed in the same pots again.—P.

NOTES ON HERBACEOUS PLANTS.

ONE is often very much interested in the notes which appear from time to time about herbaceous plants and hardy bulbs, although one is sometimes taken aback when one reads of the large numbers which some amateurs cultivate. Thus we read of hundreds of plants of *Primula rosea*, and then we think of our own little plot of two or three, and wonder whether anything we can say can be of much value or interest. But then comes the reflection, if I want to get any information for myself I look for it, not from large, but from small growers; for it is not merely that the former have these great quantities to revel in, but they have also more help, and so are able to overtake their work. Then seasons vary, and the experience of one is no guide for another; thus, for instance, this year the long-continued dry weather in spring has evidently told injuriously on some plants, which have either perished or been much crippled in their growth; and one thing has struck me very forcibly, the same character marks similar flowers all over the country. Thus I had considerable disappointment with *Iris reticulata* and its allies, but I found the same complaints were made by growers in Scotland and various parts of England.

ANEMONE PALMATA ALBA.—This has flowered very well with me this spring, and it is certainly a handsome plant. I should much like to know, however, why I am not able to manage equally successfully the type *A. palmata*. Its yellow flowers would be such a pretty contrast to the white ones that I should be glad to see them in flower together, but I never can succeed with it.

ARNEBIA ECHIOIDES.—The drought has, with me, affected this plant, for although it has grown, and is in flower, yet neither the foliage nor the flower stem is as strong as they usually are. It is a very pleasing shade of yellow, and the curious spots on the petals, which disappear after the flower has been open a few days, make it attractive, and visitors are always pleased with what is called the Prophet's Flower.

ANDROSACE SARMENTOSA.—Coming from the Himalayas, this beautiful little alpine has made large masses, which are now covered with its umbels of pretty pink flowers with white eyes. The foliage is peculiar, very silvery, and in the form of rosettes, from which shoots run out that easily take root if pegged. In winter the plant might be well taken for a Saxifrage. I see that some persons advise that it should be covered during winter with a sheet of glass, but I have never found this necessary. There is, however, another Himalayan species, *A. lanuginosa*, which, as its name implies, has very woolly foliage, and so is liable to retain the moisture and decay, and this I have always found necessary to cover over in the winter months. It is curious that one finds it much easier (at least I do) to grow these Himalayan species than our European ones, for I have never succeeded in obtaining for any time *A. carnea*, or its variety *eximia*. It is true that they are different in habit and smaller in foliage, but I have tried over and over again to keep them, and have failed.

AUBRIETIA LEICHLINI.—A large clump of this with its rosy crimson flowers has been very beautiful this spring, and is certainly the brightest, as far as I know, of this charming tribe of spring flowering plants. Its habit, too, is dwarf and vigorous, and when allowed to fall over pieces of rock forms a handsome object. There is also another vigorous bright rosy pink variety which was raised many years ago by the late Mr. Ingram of Belvoir, from whom I received it, and I am glad to retain it in my garden, not only for its intrinsic beauty, but as a memento of that good man and able gardener.

DODECATHEON MEADIA.—Why this is called the American Cowslip I have always been at a loss to understand, as its curious flowers more resemble a Cyclamen than a Cowslip. It is a lover of moist places, and hence I suppose the dry season has not suited it, for the plant which I have now had for some years is not half its usual height. It is, however, healthy, and will, I hope, recover after the heavy rains that have fallen of late.

CORYDALIS NOBILIS.—This pretty Fumitory has succeeded well, although one could hardly have expected it during this mild winter, it being a native of Siberia. It is a showy, strong-growing perennial, and deserves a place in every garden. It is rather too tall for the rockery, and is therefore better suited for the border. I do not find it at all particular as to situation or soil.

GENTIANA ACAULIS.—My experience with this lovely plant this season has been somewhat singular. I suppose that, owing to the mild winter, it bloomed rather freely in January and February, and consequently there is a scarcity of bloom now. One can hardly lay down any rule as to its position or the soil it likes, for I have seen it growing and blooming profusely in ordinary garden soil, and also in very heavy loam. I have known a garden, not at all sunny, where the borders were edged with it nearly a foot wide; the soil was a heavy loam, and anything more luxuriant than the growth or profuse than the blooming could hardly be imagined. I know also a long border fully exposed to the sun with ordinary garden soil, and here it succeeds admirably. Yet I have heard people over and over again say they could do nothing with it. That still more beautiful Alpine gem *Gentiana verna* has often been a trouble to growers of Alpine plants, yet it is a native plant, and is abundant and luxuriant in the limestone formation of the West of Ireland, where it grows from within 3 feet of sea level up to 1000 feet. I have often tried it, and often failed; but I hope my plants of it are now establishing themselves. I have planted them in the midst of *Arenaria balearica*, that charming dwarf plant with its tiny white flowers, which so soon spreads itself over the rockery. It is now showing up its flowers, and I hope it will be in bloom before the end of the month. It, of course, should not be disturbed, and this condition is somewhat like what one

has seen in the short pastures of the upper regions of the Alps, which are often thoroughly blue with its beautiful flowers.

TULIPA CORNUTA.—This is said to be a synonym of *acuminata*. It is a curious ragged-looking flower of bright colour, suited for the border, where it is always sure to attract the notice of strangers. *Tulipa retroflexa* is a very beautiful bright yellow flower, of peculiar formation. It is said by some to be a hybrid between *acuminata* and *Gesneriana*, but it bears no affinity to either of its supposed parents.

ANEMONE RANUNCULOIDES.—Much has been said of late about the beauty of this delicate little Alpine. Some persons have experienced difficulty in establishing plants, and it is one of the charms of growing herbaceous plants that one has to consult their tastes as to soil or situation to insure their growing vigorously. I have a good clump of it growing on an elevated and sunny spot on my little rockery in a light and somewhat sandy soil. It is covered with its pretty little yellow flowers dotted over its dwarf foliage. It is easily propagated, and is one of those plants which ought never to be absent from the rock garden.

PHLOX SETACEA AND NELSONI.—These form large clumps on my rockery, and are now very attractive, being covered with bloom. There are several varieties of various shades of colour, but all are attractive.

DRYAS OCTOPETALA.—This is just beginning to show its buds, and its beautiful foliage will shortly be covered with the charming white flowers. It is in a moist situation. My plant came from the West of Ireland, and has been established for some years.—D., Deal.

OBSERVATIONS IN THE HARDY FLOWER GARDEN.

THE spring garden with its flowers appeals to us with a freshness and a beauty that belong to this happy time. Its flowers are those possessing the grandeur of simplicity, seen as they are in their native habitats in bold masses. It seems to be Nature's plan to place her prostrate, low-growing plants, in broad and spreading masses, so that their pure, soft, and intense colours shall light up the landscape with beauty. It is more than strange that many of the great gardens of Britain are void of this beauty, as it should be, in bold and telling masses. True, many practise spring bedding, but this is frequently in mosaic imitations or in stars and stripes.

It is not of the flower garden proper I wish to speak, but of the filling of many corners more effectively than is frequently done. The plants I am alluding to are from their dwarfness of growth unsuitable for the herbaceous border. The subject was suggested to me by recently seeing these flowers in unrestricted masses. Mounds had been formed by huge boulders which were half-way buried in light soil and were scattered promiscuously throughout the garden. Each had one kind or variety only covering its surface.

The plants used were *Alyssum saxatile*, *Aubrietia græca*, *A. Leichlini*, *A. Campbelli*, *Saxifraga hirta*, *S. aretioides*, *S. granulata* fl.-pl., *Lithospermum prostratum*, *Arabis alba*, *A. alba* variegata, *Phlox setacea*, *P. setacea* atro-purpurea, *P. Distinction*, *Iberis corifolia*, *I. semper-virens*, and *Thymus citriodorus* foliis aureis. But language fails to describe the loveliness of the floral picture.

Before leaving this subject I should like to describe a quaint old garden in North Wales, surrounding a stately and historic house of uncertain date, whose grey stone walls were clothed with *Wistarias*, *Roses*, *Jasmines*, *Chimonanthus*, and *Magnolias*. The quadrangular flower garden had a few circular beds scattered at wide distances over the green turf, while a fountain splashed its crystal waters brought from the crags above. The flower beds were filled with "*Geraniums*" and tuberous *Begonias*, while plunged in the turf were large standard *Heliotropes* and Japanese Maples (*Acer palmatum ampelopsifolia*). Three sides of this garden were bounded by an elevated broad terrace walk, and borders on each side of the walk were planted with a choice and varied selection of herbaceous plants, intermingled with groups of hardy and half-hardy annuals. The spring flowers that I have alluded to were also here in masses, creeping over the broad stone edging, whilst in summer the fronts of the borders were enlivened by hardy annuals, sown thinly, and afterwards thinned out so as to fully develop and show off their charms.

Here waved Iceland and Shirley Poppies, *Clarkias*, *Godetias*, Sweet Sultans, Cornflowers, Corn Marigolds, *Jacobæas*, *Saponaria calabrica*, stately Hollyhocks, *Phloxes*, *Delphiniums*, *Dahlias*, *Pæonies*, *Gladioli*, *Rudbeckias*, *Helianthus*, *Coreopsis*, *Anemone japonica*, *Anthericum*, *Gesnerian Tulips*, English and Spanish *Iris*, *Campanulas*, *Alströmérias*, and clumps of Stars of Bethlehem, *Schizostylis coccinea*, and *Violas* in many colours. Here was beauty of effect, and one might gather great armfuls of flowers for room decoration without spoiling the effect.

The fourth boundary was a railing of iron, and in a border below on the opposite side were planted and trained over the railing *Clematis montana*, a wealth of starry white flowers in May; *Clematis Jackmanni*, *C. Henryi*, *C. Lord Neville* (a pure azure flower), *C. vitalba* lit up the autumn months, and the *Gloire de Dijon* Rose grew and flowered luxuriantly.

How different the effect of the terrace borders here mentioned from some that are too frequently seen, and from which scarcely a flower can be cut, planted, as they are, with straight lines—ribbon borders, as we are pleased to call them. A back row of *Suntowers* and *Dahlias*, with lines of *Perilla nankinensis*, *Ageratums*, "*Geraniums*," yellow *Calceolarias*, and *Cineraria maritima*. I do not mean to disparage these summer plants, but could not a place be found for them in the herbaceous borders, or in beds in distinct masses?—F. STREET.

WEATHER IN LONDON.—Though during the past week a considerable amount of rain has fallen, we have had the first touch of summer weather. On Thursday and Friday, with Sunday morning, we had heavy showers, but the afternoon and evening of the latter day were fine. Monday opened brilliantly, but a steady downpour came later. Tuesday was a glorious day, and Wednesday opened dull but fine.

WEATHER IN THE NORTH.—June has begun with a week of very changeable weather. Generally there has been a higher temperature, with a good deal of rain. Monday was very gloomy, and rain fell steadily nearly the whole day, but Tuesday morning was bright and extremely pleasant.—B. D., *S. Perthshire*.

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, June 14th, in the Drill Hall, James Street, Victoria Street, Westminster, 1 to 5 P.M. This will be the first meeting, at which the Sherwood £10 10s. silver cup for annals and biennials, decoratively arranged, will be competed for. A lecture on "Hybrid Orchids" will be given by Mr. James O'Brien, V.M.H., at three o'clock.

NATIONAL DAHLIA SOCIETY.—Mr. J. F. Hudson, The Gardens, Gunnersbury House, Acton, the Hon. Secretary, favours us with a copy of the official catalogue of the Society, which is offered to non-members for 1s., plus about 1d. for postage. It is a very useful and comprehensive compilation that ought to be in the hands of every Dahlia grower, but is, perhaps, more particularly valuable to those who enter the competitive arena. All varieties worthy of inclusion are noted, with a description of the colour and the height of the plant, while at the end is an alphabetical list of varieties with the raisers and the year of introduction. Applications for copies should be made to Mr. Hudson, as above.

CYTISUS KEWENSIS.—This is one of the best additions to the list of hardy flowering shrubs which has been introduced during recent years. It originated at Kew, and is a hybrid between *C. Ardoini* and *C. albus*. It flowered for the first time four years ago, and has continued to improve until it now ranks with the showiest of the family. It is of prostrate habit, making long shoots which form a perfect mat. The flowers are of a soft sulphur colour, and are produced with such freedom as to perfectly hide the branches. For covering a bank, for a bed, used as an undergrowth—where it will get plenty of light—or planted on the rockery, it is equally effective.—W. D.

A GOOD FLAVOURED POTATO.—A great difficulty is present at this time of the year in obtaining Potatoes of good flavour. Many varieties eat well when dug, and for some time afterwards; but when kept till late in the spring their good qualities depart, and new Potatoes are welcomed because old ones will not cook. I am now testing the eating qualities of Universal, a round maincrop variety, and in comparison with other well-known sorts find it to be superior. The tubers have kept quite sound, and when boiled are of excellent flavour, mealy, and floury. The Potato-buying public are beginning to know the names of varieties of good eating qualities, and these are frequently asked for. Anyone to whom flavour in Potatoes is the first consideration will do well to give Universal a trial.—H. H. G.

WAR WITH WEEDS.—An old proverb and a very true one is "One year's seeding, seven years' weeding;" for if weeds are allowed to grow large, they require ten times the amount of labour to exterminate them than when constantly attacked and kept rooted-up whilst in a small state. I consider that to allow them to seed is a very serious error, for once allow them to get up, it is not a mere hoeing that is required, but a thorough raking and cleaning afterwards, and this is undoubtedly labour thrown away. A small amount of labour judiciously applied in this work does more towards thorough cleanliness in the garden than a vast amount at the wrong time. The Dutch hoe should be systematically and frequently used between all kinds of garden crops during the growing season, choosing bright dry weather for the operation. It is surprising the amount of ground a couple of good labourers will cover in a day. This constant persistence with all kinds of weeds, including the more noxious kinds, such as Bindweed, will eventually exterminate them entirely for the season.—H. T. M., *Stoneleigh*.

DEATH OF MR. S. SPOONER.—We regret to have to record the death, on the 3rd inst., of Mr. Stephen Spooner, of the Hounslow Nurseries, at the age of seventy-five.

THE CANTERBURY HOE.—I find the Canterbury hoe a useful tool for earthing Potatoes and other vegetables. With the soil previously loosened between the rows, two rows of Potatoes may be earthed up at one operation—that is, by working the hoe down the centre between two rows the soil is drawn on each side. In moist weather loosening the soil previously to earthing may not be necessary, and the hoe may be used in the same way as an ordinary draw hoe, but with less labour.—E. D. S.

NORTH WING OF TEMPERATE HOUSE, KEW.—From the "Kew Bulletin" we learn that the contract for the erection of this building, which will complete the whole structure in accordance with the original design of Decimus Burton in 1860, was entrusted by the First Commissioner of her Majesty's Works and Public Buildings to Messrs. Mackenzie & Moncur of Edinburgh. It is hoped that it may be completed during the present year. It is proposed to devote it to Himalayan and cool temperate New Zealand plants.

GARDENING APPOINTMENTS.—Mr. G. W. Cummins, late head gardener to A. H. Smee, Esq., The Grange, Wallington, Surrey, has been appointed by W. H. Lumsden, Esq., to a similar position at Balmedie, Aberdeenshire. Mr. Cummins is a sound gardener, and many Southern friends will regret losing his quiet and effective co-operation in charitable and other worthy objects. Mr. Samuel Weston, late foreman at Berwick, Shrewsbury, has been appointed head gardener to Colonel Wood, The Willows, Newton-le-Willows, Lancashire.

ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of the Society, to be held in the rooms of the Royal Astronomical Society, in the Quadrangle of Burlington House, Piccadilly, W., on Wednesday, the 15th inst., at 4.30 P.M., the following papers will be read:—"Frequency of Non-Instrumental Meteorological Phenomena in London with Different Winds from 1763 to 1897," by R. C. Mossman, F.R.S.E., F.R.Met.Soc. "Progress of the Exploration of the Air by Means of Kites at Blue Hill Observatory, Mass., U.S.A.," by A. Lawrence Rotch, M.A., F.R.Met.Soc.

DUTCH HORTICULTURAL AND BOTANICAL SOCIETY.—At the meetings of the Floral Committee on March 9th, April 20th, and May 11th, 1898, first-class certificates were awarded to Messrs. V. Schertzer & Sons, Haarlem, for *Primula veris acaulis cœrulea* (March 9th); to the botanical garden of Utrecht for *Cineraria Lynchi*; to Mr. Baron van Boetzelaer, Maartensdijk, for *Eulophiella Elisabethæ*; and to Mr. A. D. den Older, Leiden, for *Plantago lanceolata fol. varieg.* A certificate of merit was given to Mr. Baron van Boetzelaer, Maartensdijk, for *Stanopsis (Vanda) gigantea*.—H. C. ZWART, *Secretary*.

ISLE OF WIGHT.—The monthly meeting of the I.W. Horticultural Improvement Association was held at Newport on Saturday last. Dr. J. Groves, B.A., J.P., presided over a good attendance. Through the indisposition of Mr. F. W. Shrivell, Tonbridge, his place was taken by Messrs. S. Heaton (Hon. Sec.) and F. Midlane. The former read a short paper on "Bees," dealing with their uses, structure, natural history, and management, whilst Mr. Midlane exhibited and explained various bee-keeping appliances. For the appliances he received a certificate, as did Mr. J. E. Watts, Sunbury Gardens, Middlesex, for a patent watering-can. Votes of thanks were accorded to Messrs. T. Collister (Bembridge) and G. Williams (Gatcombe) for collections of *Aquilegias*. At Newport Nurseries Mr. A. E. Cave has a fine collection of pot Strawberries, the best being *Auguste Nicaise*, *Royal Sovereign*, and *Noble*.

THE CUCKOO AND CATERPILLARS.—I do not know whether the cuckoo is usually reckoned amongst the gardener's feathered friends, but he has been of great service to me the last two years in protecting Gooseberry and Currant bushes from the ravages of the caterpillar of the magpie moth (*Abraxas grossulariata*). The trees were badly infested and last year, frequently noticing a cuckoo in the fruit quarter, I carefully watched its movements, and to my satisfaction found it was after the caterpillar, and cleared the bushes completely of the pest. This spring my friend, or one of the same species, has returned and is carrying out the same useful work with good effect, saving a great deal of labour at a time when every minute is precious to a busy gardener. Although the cuckoo is generally a shy bird, I can approach within 10 or 12 yards of my helper without disturbing it. I should be glad to know if other gardeners have had similar experience. Henceforward the note of the cuckoo will not only be the harbinger of spring to me, but the voice of a valued friend.—W. C. STONE.

— **EARLY POTATOES.**—Mr. J. V. Leadbetter, The Gardens, Tranby Croft, Hessle, East Yorks, writes:—"Notwithstanding the unpropitious nature of the spring season, you will be astonished to hear that to-day, June 1st, I have dug over 2 lbs. of new Potatoes from the open border. For East Yorkshire this is, I think, a record accomplishment. Three kinds—viz., Sharpe's Victor, Britannia, and the new American called 'Bovee,' the latter being the best cropper, but Sharpe's Victor takes preference in point of earliness; several tubers of the latter kind measuring 2 inches in length, and 5 inches in girth."

— **CARDIFF HORTICULTURAL SOCIETY.**—We have been favoured with a schedule of the Show to be held in the Sophia Gardens, Cardiff, on July 20th and 21st. We find particulars of upwards of 120 classes, of which some are open, while others are subject to various restrictions. In several of the classes the prizes are generous, and should bring forth keen competitions from the many excellent growers in the West country and the principality. This is the tenth show of the Society, and full particulars may be had from Mr. H. Gillett, 66, Woodville Rd., Cardiff, the Secretary.

— **A FRUIT TREE PEST.**—I notice fruit trees, especially stone fruits, are being injured by a maggot, about three-eighths of an inch in length, dark brown in colour, with a black head. It attacks the tips of the tender leaves, and forms them into a bunch, thus preventing for the time extension of the shoot. The best remedy appears to be hand-picking, though this can only be carried out on a small scale in most gardens, time not allowing for a thorough examination of every tree. From the fact, however, that the shoot afterwards produces fresh growth, I am led to suppose that the enemy undergoes some change, it may be into the chrysalis state, from that to emerge into a moth later on in autumn, the moth in its turn laying its eggs deep down in the buds, to be naturally covered over as the bud develops, and thus protected during winter, hatched out the following spring. Is this so? If any able writer, such as Mr. Abbey, would kindly give the life history of this pest, and suggest preventive measures, the information would be of service.—T. P.

— **MR. PETER BARR IN NEW YORK.**—The New York Gardeners' Society met recently. One of the features of the meeting was the distribution of medals and certificates. In the absence of Mr. D. Turner, who was to be the speaker of the evening, his paper on "Lettuce Forcing" was read by Mr. R. Angus. Quite a lively discussion followed, in which Messrs. A. Herrington, W. Scott, and James W. Withers took part. Mr. Peter Barr, V.M.H., of London, who was present, also spoke, and very highly praised the black-seeded head Lettuce named *Petite Noir*, which was exclusively used by French growers for the Covent Garden Market. Other points brought out were: that Lettuce should be grown in a temperature of about 45°; that tobacco stems should not be used in fumigating, but rather tobacco dust—this last-named being more effective against insects, and less liable to injure the leaves. The system to follow, the placing small heaps of the powder on the paths, and igniting these by the aid of a tablespoonful of kerosene, and then allowing them to smoulder.—("American Gardening.")

— **THE RATING OF GLASS HOUSES.**—A meeting of the glass house owners in the Dartford Union was held at the Bull Hotel, Dartford, a few days ago, Mr. Emerson of Hextable in the chair. The Chairman said they would have been glad to have left the assessments as they were, but the Dartford Assessment Committee seemed to have formed a conclusion, he did not know upon what grounds, that the horticultural industry was a gold mine. If they had accepted the increased assessments that the Dartford Assessment Committee wanted to impose on the glass houses and nurseries it would have meant almost the annihilation of the industry. Considering the competition that now existed, and was likely to increase, with such conditions as were imposed they could not have made things meet; therefore they were compelled to take the action they did. He traced the history of the appeal, the result of which was that the assessments were reduced 63 per cent., or 8s. 6d. in the pound. This successful result had not been brought about without a great deal of expense. Mr. Ayres, Swanley Bottom, gave some particulars showing what benefit they had gained by the appeal. In the first place, it was established that all glass houses should be rated by the amount of land they covered, and the structure not taken into value. A glass house 100 feet by 12 feet had thus been reduced in net rateable value from 75s. to 42s. 6d., so that a grower having twelve houses of these dimensions would save £25 16s. in rateable value, and if the rate for the year in his parish averaged 5s. in the pound he would save £6 7s. 6d. per year. Mr. Ayres said that thus one year's savings by the appeal would cover the cost of the litigation. The Chairman suggested the formation of a Glass House Owners' and Occupiers' Association, and said he hoped those present would give it their consideration.—("South-Eastern Gazette.")

— **MAY WEATHER AT DRIFFIELD.**—Mean temperature at 9 A.M. (corrected), 51.03°; wet bulb, 47.89°; mean maximum, 55.84°; mean minimum, 40.94°; highest, 62.2° on the 22nd and 29th; lowest, 32.8° on the 15th. Mean of maxima and minima, 48.39°. Mean radiation temperature on the grass, 38.09°; lowest, 31° on the 7th and 13th. Rainfall, 2.555 inches. Number of rainy days, eighteen. Greatest amount on one day, 1.04 inch on the 20th.—W. E. LOVEL, *Observer, Driffield.*

— **SUSSEX RAINFALL.**—The total rainfall at Stonehurst, Ardingly, for the past month was 3.77 inches, being 1.82 inch above the average. The heaviest fall was 0.65 inch on the 13th. Rain fell on twenty-one days. The maximum temperature was 69° on the 22nd, the minimum 32° on the 13th. Mean maximum, 57.05°; mean minimum, 48.04°; mean temperature, 52.54°, which is 0.98° below the average. Since May came in the season has completely changed, and a little more sun would be welcomed. There has been no frost to hurt fruit, and there is promise of a full crop.—R. I.

— **THE WEATHER IN MAY AT HODSOCK PRIORY, WORKSOP, NOTTS.**—Mean temperature, 50°. Maximum in screen, 69.1° on the 23rd; minimum in screen, 32.9 on the 13th; on grass, 24.7 on the 13th. Number of frosts in shade, 0; on grass, 14. Sunshine, 144 hours, or 30 per cent. of possible duration; difference from average, - 30. Rainfall, 2.12 inches; difference from average, - 0.24. Rain fell on seventeen days. Rainfall since 1st January, 7.24 inches; difference from average, - 1.97. Month cool, especially in the daytime. No warm days, but no severe frosts. Showery, but total rainfall not quite up the average.—J. MALLENDER.

— **NEW YORK BOTANICAL GARDENS.**—We learn that these gardens are about to be enriched by the erection of a range of thirteen glass houses, which it is estimated will cover an area of 45,000 square feet. The houses will enclose a large court, which is to be utilised for the cultivation of aquatic plants. The central feature of the southern front of the range will be the large circular Palm house, which will have a diameter of 100 feet, and a height of 90 feet. The wings running east and west from this will be 30 feet wide, 116 feet long, and 26 feet high, measuring to the ridge, and they will be terminated by more roomy erections 46 feet high and 84 feet wide. The connecting houses which run south from these will be lower, measuring 30 feet in width by 75 feet in length, terminated by two domed, square houses 50 feet in diameter, and 35 feet in height. These are in their turn joined by two more low houses, each 38 feet in width and 103 feet in length. The heating apparatus will be sufficient to maintain an atmosphere of 70° Fahr. whatever the weather, and the houses are to be all well supplied with hot and cold water.

— **RAMPION.**—It is very unusual to find this grown in the vegetable garden, although in some large establishments it is occasionally inquired for. On account of the minuteness of the seeds it is no easy matter to get a good bed, especially in dry periods. It is almost as fine as the Begonia in its seeds, a fact that renders even shallow drills unnecessary, so far as the need of soil for covering is concerned. Sow seeds immediately for next winter's crop, where a demand exists, or where an addition to the list of root vegetables is favoured. Sown too early they are prone to run to seed; the plants when in bloom much resemble the taller wild forms of *Campanula*. Scatter the seeds thinly on the surface of a bed made moderately firm, and very fine, or the seeds would probably be too deeply buried to germinate. Fresh manure is best avoided, or it would have the same effect as is common to all root crops. That manured for a previous crop would be in good condition for the growth of Rampion. Choose, if possible, a showery time for sowing, and prevent the weeds from suffocating the tiny plants.—W. S.

— **DEVON AND EXETER GARDENERS' ASSOCIATION.**—The summer outing of this Society, which will, by favour of the Duke of Bedford, be Endsleigh, one of the most charming family seats in the county. The excursion will therefore be to Tavistock and Endsleigh, on Wednesday, the 6th of July. The L. and S.W. Railway have been good enough to undertake to provide saloon carriages for the party to and from Tavistock; and Mr. Squire, of the Bedford Hotel there, has arranged to drive the visitors to Endsleigh and back in brakes. The party will leave Queen Street Station at 9.5, and reach Tavistock at 10.45. Opportunity will then be taken to inspect the various interesting memorials in that historic town, and at 12.30 a light lunch will be served. The brakes will leave at one o'clock for Endsleigh, where two hours will be spent. On returning to Tavistock a substantial meat tea will be served, and the return journey be made from Tavistock, leaving at 7.55, arriving at Exeter at 9.28. Tickets to members, including railway and brake fare, light lunch and meat tea, 7s. 6d.; tickets, friends of members, 10s. All tickets must be taken by Friday, 1st July. No tickets will be issued at the station.—ANDREW HOPE, *Hon. Sec.*

ARUM LILIES.

THE cultivation of the Arum Lily is an ever-recurring topic, and at the present time pot culture as opposed to planting out during the summer months, after having been in abeyance during a quarter of a century, appears to be coming again into vogue. At least, it is not without its advocates, who find in it a cultural system adapted to their particular requirements. Pot culture has the doubtful advantage of age, for it is recommended by eighteenth century writers like Hill and Miller, by whom the Arum, or Sweet Calla, as it was then called, was treated as an evergreen tuberous plant, which, though exotic, was all but hardy.

I am inclined to think that the planting-out system brought to view the full value of the Arum as a decorative plant, as well as being the means of showing the facility with which it could be cultivated. Its very responsiveness to the most careless treatment has led to its being grown in ways that cannot be generally recommended. As an example, I have seen the plants placed almost close together, remaining in the same position the year round, the aim of the grower having been to secure the largest possible number of small spathes at the lowest cost for production. Another instance is that of a very successful grower whose plants are never in a pot at all. They are transplanted from the open in autumn into long low structures, where by regulating the temperature the grower can retard or bring them on rapidly at will. After the Easter gatherings the plants are slightly hardened, and then transferred again to the open to remain until the succeeding autumn, when the above mentioned process is repeated. Than this, I have seen no cheaper method of producing good spathes plentifully.

In private establishments where plants for furnishing as well as flowers for cutting are in constant demand during the winter months, it is impossible to employ either of the above methods. We are, in fact, practically confined either to the resting system in pots during summer, or to planting in the open for the summer months and potting in autumn. I agree that in cases where flowers and plants are not required except at some special season, say Easter, pot culture may have the advantage, as in such a case the plants can be brought slowly forward, and sturdy, well-furnished specimens, be the result. But in those cases—and I infer they are the most numerous—in which a long continued supply must be provided, then I have no doubt as to summer planting being the better system. I have adopted it for the last quarter of a century, with the result that in most years we cut in November, always in December, and the supply in spring is only stopped with the demand for the spathes.

At present our stock is being planted out for the summer. Many unopened spathes are still upon them, and would have been cut with others, only since Easter the plants have been standing in an open shed, and naturally growth has been all but at a standstill. The plants are put in ordinary garden soil, those that require dividing being split up at this time and single growths selected for potting in 6-inch pots, a size I find very useful for furnishing. If the soil is dry when planting is effected water is given them, but as genial humid weather is chosen for the work, as a rule watering is not required. The plants are left to themselves till September, when with a spade the roots are cut and the plants slightly raised. The object of this is at once to check growth in the plants, to induce a rapid development of spathes, and to produce such a condition generally, that when lifted and potted ten days later, they feel no bad effect. I am so convinced of the importance of the plants being properly prepared for lifting, that I attribute any slightly erratic behaviour in flowering to this part of the treatment having been carelessly performed. We report about the third week in September, and use small pots in comparison to the bulk of roots. Any good holding soil suits, and without sand or leaf soil. The plants are returned to the forcing houses in the second week of October, having in the meantime stood in a shaded position out of doors where, root action having commenced, it is possible to force the more forward plants at once into flower, and without doing them injury.

Owing to the many roots with which each plant is furnished I find it necessary to apply slight surface dressings weekly of some manure. The foliage as well as the flowers being of much beauty of form, plants are always in request for standing in apartments. The chief thing to guard against there is root dryness; apart from this I have never found plants seriously injured. At Christmas and Easter plants in church invariably suffer, but it is only because they cannot be watered. The spathes are highly valued for vase-filling. I prefer them arranged with no other flower, and it may here be remarked that they should only be employed when young. If short of material half-opened spathes are as valuable as those fully expanded, inasmuch as they are distinctly beautiful in themselves, and full expansion quickly takes place, while such spathes always last longer in good condition than those cut older.

With regard to the hardiness of the Arum Lily, it belongs to that exasperating class which, under certain conditions, will stand a few

winters safely. I have known the foliage pass 7° of frost without damage, and in some localities the plants thrive year after year when grown in water. It cannot, however, be depended upon, and it is better to house plants in the autumn previous to the first sharp frost, and in spring to defer planting till frost is past for the season.—R. P. BROTHERSTON.

PHLEBODIUM MAYI.

THE exhibit of Ferns from Mr. H. B. May at the Temple Show was rich in handsome forms, but amongst them all *Phlebodium Mayi* stood out as one of the most conspicuous. It is perfectly distinct from all other *Phlebodiums*, even from *glaucum*, from which in all probability it has issued. The fronds, as may be seen in the woodcut (fig. 90), are graceful, wavy in outline, and are chastely divided. They are frilled and serrated at the edges, and of a peculiar glaucous grey colour in the centre, that is extremely effective. Beyond this shade there is a broad margin of bright green, that materially enhances the beauty of the plant. The specimen staged by Mr. May was, we were informed, only about six months old, from which we should gather it is the possessor of a vigorous constitution. *P. Mayi* elicited the admiration of everyone, and is sure to become highly popular. The Floral Committee of the R.H.S. accorded a first-class certificate to the plant, an honour that was thoroughly deserved.

SPRING TRENCHING AND ITS RESULTS.

IT is a capital thing to put a theory into practice, especially if you do not believe in it. Some time ago it occurred to me that it would be an admirable idea to give Mr. David Thomson a fair trial, and far better than arguing on paper. I therefore dropped discussion and laid myself out for work. The result has been disastrous, both for my able opponent and myself—for the former, because so far as this case is concerned his arguments fail; for myself, because I have spent a good deal of money without sensibly ameliorating the soil. Just to show you what late trenching means in my case, I send you a modest chunk. There are plenty more like it. It refuses to crumble, wet or dry, and nothing but a thorough freezing will do it much good. We gave it ash, grit, and muscle. I think the junior Editor saw this land when the men were at work. One of these days I hope the senior will come along, and if he happen to have Mr. Thomson with him he will be additionally welcome. In default of helpful suggestions from them I shall pin my faith to another old veteran, of the name of Nature, next winter.—W. PEA.

[Ash, grit, and muscle are excellent for ameliorating strong land, so is frost for shattering it. The question is whether frost does not do this as effectually when the land is left undug during the winter as when it has been subjected to muscle treatment in the autumn. The sample sent resembled externally a mass of brown putty, but on breaking it we found it decidedly amenable to improvement, and under the combined influences of ash, grit, muscle, and the "old veteran—Nature"—it will form a splendid medium for growing fruit, flowers, and vegetables. There was not sufficient frost last winter to act on it beneficially in a south coast county, whether in a dug or undug state. On asking the junior Editor, who is acquainted with the district, when he should dig such land he replied, in a worldly wisdom sort of way, that he should not dig it at all, as the pen was easier to work than the spade, and paid him better. If the senior and Mr. D. Thomson should bear down on Mr. Pea during a coasting trip in the good ship "Journal of Horticulture" he would find a pair of old salts, and one of them perhaps rather a hard nut to crack. We have had in hand for some weeks the following communication. It was put aside during a period of pressure and taken off the bill of fare *pro tem.* in favour of other dainties to meet the varied tastes of a multitude of welcome guests for whom we are privileged to cater. The moment does not seem inappropriate for placing the dish of digging once more on the weekly menu.]

MR. F. DUNN (page 106, February 3rd) seems to be a rather clever man. It is not necessary to find fault with his practice of digging strong soil when it is dry (an important provision) in the autumn because it has answered with him. It has, no doubt, answered with others, but neither he nor they are competent to pose as authorities until they have tried both autumn and spring digging of such soil over a series of years, and not in one district only. If Mr. F. Dunn works in a district where the rainfall is below 25 inches or thereabouts, and he keeps off the land when it is wet, his task will be an easy one, dig whenever he may.

He is particular in saying he would not dig in midwinter, but in the autumn, while another correspondent is equally explicit in saying

(page 120, February 10th) that he would not dig in the autumn, but in winter. As a matter of principle, not to say "philosophy," which seems too much for them, both these correctors of a gardener, whose experience probably either might envy—though they may feel themselves his superior in intelligence—both these "young minds," if both are young, as one confesses himself to be, cannot possibly be right, and consequently one of them must be wrong. Mr. Dunn will say it cannot be him, because he knows from "experience," and Mr. Pea may retort that he, from experience, knows also, and knows better. If they would be content to rely on the results of their practice they would be rather strongly entrenched, but neither of them can let

make them wetter and colder? It is a recognised fact, says Mr. Dunn, that dug soil will retain more moisture than that which is allowed to remain unbroken. Then why (apart from convenience) break up retentive soil till favourable weather occurs, and the ground is wanted for use? If there has been frost, it will have been frozen even more deeply than if it were light—i.e., thrown up, roughly or otherwise; and we really cannot help it if we would. According to his own showing, then, though he does not appear to see it, the ardent young philosopher increases the wetness, and lowers the temperature of his cold wet land by digging long before the time for sowing and planting. This is because it must be so, though he does not mean it so to be

FIG. 90.—PHLEBODIUM MAYI.

the "philosophy" alone, even if they do feel it to be something of a ghost. It reminds of the moth and the candle. They whirl round it, make a dash at it, but do not put it out; on the contrary, they might get singed—just a little. Mr. Dunn cannot, for the life of him, see why frost should penetrate deeper into firm soil than loose soil. That is very likely. He is not, to coin a word, sufficiently philosophised, but it is hoped he will be some day. Really, Mr. Thomson told him, but he did not see it. He will see it when he has studied the principles of density and conduction till he, to a fair extent, comprehends them; but he must have time. He cannot deny the facts, or if he did, they would remain the same until long after he has done digging, his lump of soil or lump of self-reliance notwithstanding.

It is rather interesting to note how both these champions (each of which disclaims the methods of the other) so innocently give themselves away. What is the reason why clay soils are so unworkable in the spring, the growth so slow in them, and crops so late? Fancy asking such a question, since everybody knows, or ought to know, it is because such soils are cold and wet. If that is so, as it is, why

nor does it appear to matter very much in his particular case, though it matters very seriously where the winter rainfall is perhaps twice as great as that of which he has experience.

Then Mr. Pea says it is indubitably true that a loose body of material holds more water than one that is solid. Yes, it is. He goes on to say that water expands in freezing. It does; and, therefore, he reasons, the more water in the soil the more ice, and the more completely, in consequence, the soil is shattered. Let this also be granted; but do not at the same time forget that an equal amount of frost will convert the quite sufficient, and often too much, moisture in firmer undug soil into ice, and shatter every particle of the surrounding medium just as well, while the water will pass through it much more freely than if it were made loose by digging. The purpose is then served, the desire accomplished.

Another question then arises, and a most important one. It will, perhaps, be generally conceded that the more water there is in strong soil in the spring the more unfavourable it must be for purposes of cultivation. What becomes of the greater amount of water that must

result from the greater amount of ice in a loose than in a firm body of soil? If it were not blown out by the force of expansion, as by an explosion, it must obviously remain in till the excess can pass away, in part by filtration into the subsoil (if this be porous), in part by evaporation into the air. Out the excess must go, by one or both processes, before the temperature of the soil can be raised a single degree to fit it for the germination of seeds or the extension of roots of plants and crops.

If, as in many instances, the process of filtration is tediously slow, in some cases almost nil, what is the effect? Where the amount of water is very great, as in retentive soil made as loose as possible before the winter, we have a spring puddle. There can be no other result. We have then to trust to evaporation for dissipating the accumulation, and all the time this process is in operation the land is made, not warmer but colder. The wetter it is through the greater amount of water (melted ice) in this "loose body," the longer the chilling process must be continued. It is not until the water is extracted to the extent of admitting the air—the warm air of spring—that the temperature of the earth can be raised, and crops induced to flourish. In some seasons, sites, and localities this earth-warming is a long process, growth slow, and crops late.

In many gardens which are naturally or artificially so well drained that water can pass freely down by filtration, and where the rainfall is comparatively low, the roughing up of strong soil in the autumn or early winter, when the surface of the ground is dry but not frozen, has answered very well. Most gardeners, in view of spring emergencies, like to have as much digging and trenching done before Christmas as possible, and where the practice meets all requirements it will be continued. But there are other soils and districts in which the land is heavy, rainfall great, sunshine sparse, and springs late. Under such conditions the most successful gardeners have found by experience that they act the most wisely by letting the land alone in the autumn or winter, and work it when dry enough in the spring. Their practice is based on scientific facts, as indicated by Mr. David Thomson, and which are not likely to be overturned. Much more likely is it that the able younger men who at the moment think differently from one of the soundest scientific and practical gardeners of Britain, will be staunch defenders of his views on this important subject in the years that are to come.—EXAMINER.

THOUGHTS FOR YOUNG THINKERS.

(Continued from page 421.)

I DO not know of any higher ambition or more agreeable occupation for a man than to be a gentleman's gardener, in the widest sense and broadest application of the term; but are they aware of the unceasing effort necessary to qualify for it? We need not deplore the fact that modern masters require so much for their money, and it is useless to lament the privileges they have of being able to select from a crowd of applicants. This should stimulate a man to the best he is capable of, and young men, at least, are not aware of their capabilities; but once they feel that all things are possible to them, surely they will not barter their birthright for want of thought—because they do not at once fully grasp all the essentials necessary to success in this direction.

It is, I venture to think, worth while to place the position of a gentleman's gardener in as clear a light as possible, and it is one I have probably viewed from all angles of observation. In the first place it demands the highest talents which can be expressed by the head, hand, and eye conjointly, with the continual exercise of those virtues found in one of whom it was said—"His life was gentle, and the elements so mixed in him that Nature might stand up and say to all the world, 'This was a Man.'" Few can attain this ideal, may be said, but all who feel its force can aim for it. Those who aim at anything short of this had better bend their bows in another direction than that of being a gentleman's gardener, as I understand the term, with its concurrent responsibilities.

Ere turning to other matters I would again impress upon those in training for the post of a head gardener the importance of taking broader views of their vocation than those which existed in times of yore, with those details previously spoken of correlative to it. It is not absolutely necessary that a young man should accept all the teaching he sees in the best of gardens where he may be located as irrevocable dicta of the ethics of gardening. He should think, and the best cultivation of thought is expression. It is important that young gardeners should take pains to express their thoughts in writing with accuracy and in appropriate terms. Not in writing for publication only should they exercise care, but in private letters. It is easy for a slovenly style to settle into a firmly fixed bad habit, and prejudice a man at a critical moment in his career, as it has prejudiced many to the advantage of others who have, by striving in the direction indicated, succeeded in attaining a coveted object. As a

master over young men I have to this end invariably endeavoured to encourage them to think for themselves so far as was consistent under the circumstances, and it is gratifying to see a zest given to even humdrum work (if there is any in gardening), when a bright, intelligent youth feels the power he possesses to impress his personality upon it. Disappointments occur undoubtedly; but it is pleasant to turn to the credit side in this ledger of life and note some bright examples that have passed through one's hands now figuring not only as first-class gardeners, but men who have impressed their individuality upon good work to its advantage and their own benefit.

IN THE NURSERY.

Many of our lads love not the idea of spending a term in nursery work, with comparatively poor pay, plenty of hard work, and sundry discomforts to boot. Few, perhaps, enter one as a matter of choice. However that may be, the business methods employed, with other obvious considerations, put "grit" into a young fellow whose desire for action is the symptom of health, physical and mental. Perhaps even some head gardeners who have, perforce of circumstances, taken a spell in nursery work, have not eventually been devoid of some benefits derived from the change. Only as a youth, however, has my experience been in this direction, and four years so spent with others leads to the inference that a nursery is a capital trial ground for budding gardeners, some of whom, by not taking kindly to the work, get transplanted into other walks of life, leaving gardening—for its good.—AN OLD BOY.

(To be continued.)

SLUGS—THEIR INCREASE AND DESTRUCTION.

I HAVE hitherto accidentally overlooked "W. S.'s" kindly reference on page 430 with regard to gas lime as a slugicide. There is undoubtedly both a plethora of gardeners and of slugs, and I wish someone would suggest a cure for the former evil, but I fear the expedients from time to time put forward are something rather worse than useless, and I confess to being unequal to cope with it in any feasible manner. I can only congratulate the "in's" (who are happy), and sympathise with the "out's," who are not.

The plethora of slugs, in both field and garden, I attribute mainly to slovenly habits in so-called cultivation at the present time. Gardeners I know in many cases cannot help it, as they have not half the requisite assistance, and in such cases it is impossible that the necessary work can be done in the right manner at the right time. As to farmers, they cannot afford to employ as many hands as formerly, on account of the low prices of produce. The old-fashioned plan of "knocking the land about" had a great deal to do with its freedom from slugs. There are also many more neglected corners in gardens than formerly, and the headlands, hedgesides, and ditches are not kept in the same order on farms as they were prior to the eighties. We had in the good old days, of course, always "bad times," for I never knew a gardener or farmer worth anything who was content with present circumstances, as the best men were then, as now, always striving for better methods and more profitable crops.

I know that cultural errors and mistakes comprise the main of the evils resulting to crops by their natural enemies, and also recognise the fact that neither bad cultivation nor superior management will either give rise to a living organism, animal or vegetable, or in any wise destroy such when in possession; but the slatternly procedure, miscalled culture, favours the increase of the pests of crops to a serious extent. The root of the evil is easily traceable to the neglected corners in gardens, rubbishy headlands and hedgesides with unscoured ditches in fields. More, the greater breadths of Grasses and Clovers, and the laying down of land to permanent pasture to twice the extent of half a century ago, with the abolition of fallows, have fostered slugs in disproportion to their natural consumers, the birds, which have decreased in recent years to the prejudice of crops.

Such are my impressions of the cause of a plethora of slugs in gardens and fields. The winter, as "W. S." observes, has been favourable to slug breeding; but a slug can only deposit a certain number of eggs. Frost has little effect on slug eggs, for the animals take care to descend into the earth deep enough to be safe. The eggs, also, have such a tough integument that lime hardly does more than harden the "shell," for as applied it burns very little, and does not destroy the embryo. Adult slugs, as everyone knows, throw off lime from their bodies by the slime, and then pass on and soon don another coat; but repeat the dose, or let the dressing be such that it repeats itself at every "stride," and the slug succumbs to adverse fate—if the lime be fresh.

I am a great believer in the virtues of good lime, for when put on "hot," it burns the molluscs and profits the land. During wet weather the lime soon loses its causticity, hence it is useless to apply it then, though that is the time when slugs are most active and

destructive, and need stopping in their depredations. I have found quicklime dustings very useful, also dressings of soot. Why lime fails is because it has not been used "quick," but mild or long-slaked, and where soot fails to be useful it is because it is stale. When fresh it kills the slugs and also benefits the plants, for it then contains the essential ammonia. I have known lime water do wonders in killing slugs.

Fresh dry wood ashes act well, but when wet and leached they have little effect on molluscs, nor do they contain a material amount of potash for the benefit of crops.

The three articles are the only ones I have used regularly on growing crops. Of course there are other solutions besides:—1, Lime water, for which the lime must be fresh from the kiln, slaked in the water, and let stand after stirring well till clear. The others are 2, Ammonia water, 1 oz. of carbonate of ammonia in a gallon of water. 3, Potash water, 1 oz. of pearl ash in a gallon of water. In every case sprinkling on whilst the vermin are feeding, which is mostly when men are taking the needed rest from their labour, but care must be exercised in using the two latter, as plants, especially seedlings, vary much in hardiness.

Some persons like powders better, such as nitrate of soda, sulphate of ammonia, and kainit. All are good for crops during growth, using it very finely crushed in the evening, and not more than an ounce per square yard, and always keeping the "stuff" out of the hearts of the plants. Good guano also kills slugs and improves crops more in an all-round manner than any other hand manure, but it also burns plants if it get into the hearts of tender seedlings.

As for gas lime, no one has ever used it or seen it used who advises its employment on growing crops. It will kill slugs and such like, and either kill or injure the crops. Where it does no harm to growing crops is because the article has lain some time and become little more than gypsum, and is then of no value as a killer of pests; it will, however, profit crops to some extent by the contained lime and sulphur. Gas lime must be fresh from gas works, and used only on bare land some weeks before cropping. On very foul land I have used 5 tons per acre, 5 stones per rod, as soon as the land was cleared at the end of summer, or at any time in consequence of diseased crops. That was where Turnips fingered-and-toed, Cabbages clubbed, or Onions were destroyed, by maggot or fungus. It was spread on as evenly as possible, when the land was moist, but with a prospect of fair weather. It smells offensively for a time, and there it must lay for at least a month before digging in. Its virtue may go into the air to a great extent, but enough goes into the soil to cleanse it. It will cleanse the foulest land of the worst foes of crops, and that is something, without any prejudice to the crop in the following season.

In mild cases 3 tons per acre, or 3 stones per rod, put on when desired, always after a crop or on bare land when moist, leaving three weeks before pointing in, which is better than digging or ploughing in deeply. Even 2 tons per acre will do on not much infested land, or 2 stones per rod, and that let lie a fortnight, can be harrowed in or pointed under lightly with a fork. Or, as a preventive, 1 ton per acre, 1 stone per rod, left a week, then pointed under will do. Less I have not found of use.—G. ABBEY.

[The most certain, safe, and sure slug destroyer we have found is clear lime water, applied an hour after dark to seed beds, or whatever plants are attacked the most persistently. A few years ago a gentleman took possession of a neglected garden of clayey soil in the suburbs of London. He cleaned it, and looked forward to a feast of flowers and vegetables. But millions of slugs proved the masters. He was advised to apply lime water through rosed watering-cans to certain sections of his garden every night after dark, as if giving the ground, crops, Box edgings, and walks a good watering, and proceed till all the ground was covered. The overtime work lasted a week. "The best week's work," he said, "he ever had done." He repeated the process as required, till a slug was hard to find, and his garden gave him unbounded satisfaction.]

PENTAPTERYGIIUM SERPENS.—This rare greenhouse plant is seldom seen outside botanical gardens, though it possesses merits which warrant it a place in all gardens. It is a native of the Sikkim Himalayas, and is usually met with at an elevation varying from 3000 to 7000 feet. Occasionally it is found growing on the ground, but more often on the branches of high trees. At Kew a bushy plant, 3 to 4 feet in height, was recently in flower in the Cape house, and a number of smaller plants in the winter garden. The growths are slender, and thickly covered with dark green leaves. They spring from a curious flattened rootstock, which has the appearance of a large tuber. The flowers are bright red, with several distinct bars of a darker colour. They are almost an inch in length, and are produced along the under side of the upper half of each growth. It should be grown in sandy peat, in pots or pans, which have been nearly half filled with crocks or sandstone. Cuttings of half-ripened wood root readily if put in a close warm case. Anyone who gives this plant a trial cannot fail to be pleased with the effect produced by the graceful arching branches, with their abundant supply of pendulous flowers.—D. K.

ROSE SHOW FIXTURES IN 1898.

- June 15th (Wednesday).—York.*
 " 16th (Thursday).—Colchester.
 " 23rd (Thursday).—Bath (N.R.S.) and Ryde.
 " 25th (Saturday).—Windsor.

* Shows lasting three days. † Shows lasting two days.

—EDWARD MAWLEY, Rosebank, Berkhamsted, Herts.

NATIONAL ROSE SOCIETY.

THE annual report of the National Rose Society has come to hand. The book comprises the Society's rules, a list of the members, as well as schedules of the three shows that are to be held respectively at Bath, the Crystal Palace, and Halifax. There is not, apparently, any material change in the classes at either of the shows, and doubtless excellent displays will be brought together. Fears are expressed that Roses will not be good at the earlier shows, but it is to be hoped that the weather during the intervening period will be more propitious, when improvement will soon be manifest in the blooms. The first of the series of shows will be held in the Sydney Gardens, Bath, on Thursday, June 23rd.

COMMENTS ON ROSES.

I MUST thank "A. C." for his note on the so-called Yellow Provence Rose in your issue for April 7th. I think I recognise "A. C." as one of our oldest and most successful amateur growers, whose presence was always a welcome sight in the past at many Rose exhibitions. But is he not mistaken—or, rather, is not Mr. Rivers mistaken—in calling *Rosa sulphurea* a Provence Rose? By the way, this Rose is named *Rosa hemisphaerica* in some botanical works, and is placed under a distinct heading from that containing *Rosa centifolia*, to which the Provence Roses belong.

Like the Rev. H. B. Biron, I was much surprised to find the N.R. Society affiliated with shows of more than one day's extension, having a distinct recollection of seeing a rule-confining affiliated societies to one-day shows only. Looking back over several reports and sets of rules, however, I do not discover it now. When it first occurred more than one of us expressed surprise and regret. But if exhibitions of miscellaneous flowers are to contain Roses to any extent, they naturally wish to be able to offer medals of our N.R.S. This, I believe, cannot be done unless the Society be affiliated, and doubtless the authorities gave way upon that account.

How very backward our Roses are this season. I have heard from several growers to this effect, many saying it is the latest season they have known. Nor can I say much for the appearance and promise of my own. They are breaking weakly, more especially so when we consider how slow their progress has been. What Colchester can do on the 16th inst. it will be interesting to see. Most of the flowers must come from under glass, as was the case at Birmingham last year, just before the Portsmouth and Isle of Wight meetings of the N.R.S. In some cases plants on walls may be useful, but if not more forward than with us, even these will not be ready to cut.

When warm weather comes we shall be attacked by insect enemies as usual. On May 18th there was an east wind, while we had at that time sharp frosts for three consecutive mornings. I do not believe in the old saying, that an east wind conveys blight, more especially in respect to green fly; but we do find these little pests more harmful at a time when our Roses are checked by such uncongenial weather. At present, wherever possible, I would keep the hoe going freely; not so much to keep down seedling weeds, as to prevent many of our insect foes from resuming active life unchecked. The sawflies will soon be coming through, and other enemies will follow. Stirring over the surface soil is a great check to the egress of these, and also gives birds a better chance to get at them. Surface cultivation assists growth, and avoids much harm from drought.—PRACTICE.

WOODHATCH.

SITUATE close to the Brighton Road, on the margin of that large open space, Earlswood Common, and about one mile from Reigate town, looking south over some exquisite scenery, and altogether one of the most charming spots in the county of Surrey, Woodhatch was, on June 8th, the scene of a brilliant wedding festivity, the only daughter of the well-known owner, T. B. Haywood, Esq., having been married to Dr. Fripp. It was largely for the purpose of seeing the floral provision made by Mr. Haywood's able gardener, Mr. C. J. Salter, that I looked in at Woodhatch a few days since.

Here can be seen a splendid collection of Orchids, such as any gentleman in the kingdom may well be proud to possess, and which reflects the highest credit on the gardener. Outdoors are thousands of Roses, H.P.'s and Teas, old and recently worked, all in excellent condition, for Mr. Haywood is a frequent and successful exhibitor; and in another direction a huge collection of Chrysanthemums, of which, now in process of placing in 10-inch pots, there has been made an addition of some fifty or sixty novelties. These are three of the primary features of Woodhatch, but far from being all, as all forms of gardening are there in evidence, and all admirably done. It is a garden in which the cosmopolitan and wide reaching nature of the ancient and modern art can be seen, for the head has to be competent with Orchids, with Roses, with Chrysanthemums, with plants and flowers of every description, with fruit culture inside and out, with vegetables indoors and out, and indeed with everything. Still, so admirably is everything presented, that having absolute oversight in every department, it is evident that Mr. Salter is an accomplished, all-round gardener. Let us glance at his work.

ORCHIDS.

Instead of being a jumble of families, as is so commonly seen, the numerous kinds are kept in separate houses, small and large, and all lean-to's, though these may not be always the best for the purpose. Still, judging by results, it is difficult to assume that other houses could be better. Seeing here so grand a lot of plants, it is a matter for regret that a group of them could not have been seen at the Temple Show. Certainly, had one been sent, it would have shown that Mr. Haywood would have played second fiddle to no others, especially that Mr. Salter favours the setting up of Orchids in groups of kinds rather than in a mixed form. The first house, a small one, looking north, is full of *Miltonia vexillaria* in great variety, the colours ranging from the pure white of Daisy Haywood to deep rosy reds. No others have, however, varietal names, as giving them seems to be uselessly overloading Orchid nomenclature.

The next house is devoted to *Odontoglossums*, chiefly *Pescatoreis* and *crispums*, small pieces, in great quantity, that will bloom freely next year. Then follows a house in which are numerous grand pieces of *Phalænopsis grandiflora*, carrying fine spikes, with several side branches, of pure white flowers of the most beautiful description. *P. amabilis*, though less pure or large, is also a lovely Orchid. The house shows in splendid form this, one of the most beautiful of all Orchids, and admirably developed. A fourth house presents a paradise of *Odontoglossums*, chiefly *crispums*, in profuse bloom, spikes of huge flowers and richest colouring standing out in wonderful profusion on both sides. The hues range from pure white to rich rosy lilac, and many of the flowers measure 4 inches across. Some have smooth edges, some are fimbriated, all are most beautiful, but some are exceptionally so. Intermingled with these are fine *Masdevallias*, such as *Veitchi*, *Harryana*, *Lindeni*, *rosea*, *igneae*, and the quaint-shaped *Schlimi*. These give lovely hues of colour, especially the rich purplish *Harryana*, the spathes of which are very fine. There is an *Oncidium macranthum* that has thrown out a spike 15 feet long, and has not yet opened a bloom. Altogether this house is indeed an Orchid bower of beauty.

Now comes a long house with a south aspect largely filled with *Cypripediums*, of which there are *Schrödera*, *Lawrenceanum*, *Rothschildianum*, *Dominianum*, *Exul*, *Mastermaniana*, *Victoria Marie*, the stems branching; and not least, a superb batch of *bellatulum* in 10-inch pans full of bloom, the flowers large, massive, and richly spotted. Rarely can a finer lot be seen anywhere. The collection comprises most of the best forms in cultivation, and many are in fine bloom. In this same house *Vandas suavis* and *teres* are in bloom, fine pieces, also *Aërides*, *Saccolabiums*, and others are here.

Then follows a similar house devoted to *Dendrobiums*, of which there is a large number of fine plants, though not now in bloom. Mr. Salter shows with pride a fine lot of seedlings in pots, many in 48's, having growths 12 inches high, and others in 60's, but all growing like weeds, and beautifully fresh and clean. Many of these it is hoped will bloom next year. The larger portion are only two years from seed. Here *Thunias Marshalli*, *alba*, and *Bensoniæ*, the former having ten spikes of flowers, are very striking.

The final house, also a long one, is full of *Cattleyas* and *Lælias*. Of the former, *Mossiæ* gives some splendid varieties; *Mendeli*, *Skinneri*, one form having a pure white throat; *gigas*, *Schrödera*, and others. *Lælia purpurata* is particularly fine, and has intensely rich coloured lips. There are several of these blooming superbly. Thus, roughly, enough has been said to show that the Woodhatch collection is a very fine one, and must have been to the wedding guests a source of wonder as of gratification. Passing many other plants grown for house decoration, for the supply of cut flowers, and all those uses to which plants are put in quantity, including *Caladiums*, notably *Gaspard Croyer*, which

has leaf colouring of blood red and is most brilliant, we pause at the following kinds:—

CANNAS.

Modern varieties of these plants are here in large variety, and finely grown; they are rapidly coming into bloom in 10-inch pots. Very fine is *Sophie Buchner* (fiery crimson), *Kaiser Wilhelm II.*, *Antoine Barton*, *Konigin Charlotte*, *Italia*, *Cheshunt Yellow*, *Austria*, *Alphonse Bouquier*, *Souvenir d'Antoine Crosy*, and others. The collection will make a brilliant show in a week or two. In this range of houses Carnations are grown in great numbers in pots, and there are still many more of them planted outdoors.

HERBACEOUS CALCEOLARIAS.

Now full with a blaze of colour is the span house, which is devoted to *Pelargoniums* in the winter. The *Calceolarias* are chiefly in 9-inch pots, the plants from 14 to 16 inches in height, and from 20 to 24 inches through. The flowers are large, variously and superbly coloured, the spotted forms being most appreciated, the foliage is good and clean. They are from seed sown in June last, and could not be excelled by any other private collection. In a frame there are a few scores of *Zonal Pelargoniums*, already in 6-inch pots, and now being so sturdy, have the points rubbed out to induce bushy formation. These, of some twenty-five varieties, will make this house a mass of glorious colour in November next and through the winter.

GLOXINIAS.

An entire house is filled with these lovely flowers, a superb strain chiefly from the firm of Messrs. Veitch & Sons. Mr. Salter has good reason to be proud of the display, for there are in it many grand varieties. Colours and markings are, as usual, very varied; but form is of the finest. Very richly coloured is *Irma*, intense scarlet; *Mrs. Donaldson*, fiery crimson; *Evalina*, blue, white margin, and others. A plant or two of *Sutton's Her Majesty* shows the finest pure white in cultivation, and is a grand companion variety to *Veitch's* fiery colours.

STREPTOCARPUSES.

These have for several years been a marked attraction here, and a lean-to house is devoted to them. There are scores of fine plants in from 6-inch to 8-inch pots profusely blooming, inclusive of pure white; also white with striped throats, lavender, blue, purple, violet, carmine, red, and maroon, all in exceeding beauty. Probably this batch of *Streptocarpus floribundus* would present a very special attraction to many persons, because they are more easily grown by the amateur than are Orchids or many other things mentioned. But whilst they attract so much admiration and are so beautiful, they further serve to show how much can be done by skilful cultivation.

ROSES.

Of these there are, as I have said, thousands. Near the house a long border is devoted to Teas, but the greater portion, and all the H.P.'s, are in the lower grounds adjoining the fruit and kitchen garden. The whole of the plants, old and new, are throwing up sturdy shoots, and promise to carry later very fine flowers. It says much for the gardener's capacity and application that he is able to enter the lists at Rose shows with the *Lindsells*, *Pembertons*, *Grahams*, and other great rosarians without discredit, yet he has a hundred other things to see to. The Dog Rose is the primary stock used, being made from cuttings. The whole of the Rose breadths, very extensive ones, are as clean as a new pin. It seems difficult to conceive of better culture, and doubtless the results are commensurate.

CHRYSANTHEMUMS.

Mr. Salter, as his successes here and there at leading shows have testified, is one of the best growers and exhibitors in Surrey, and that almost in this case means England. This leads to the remark that another first-class exhibitor, Mr. A. Mease, of Woodside, Leatherhead, is a capital rosarian also, and especially a first-rate all-round gardener. I mention this to show that the most able of Chrysanthemum growers need not necessarily be a specialist, and generally is not. The Woodhatch plants, of which there are some 600, were the other day being placed in their final pots, the plants being generally from 18 to 24 inches in height, and having sturdy hard stems. The collection will be a most interesting one to see next autumn, because of the many novelties in it, and which are certain to be well grown.

FRUIT.

Indoors there are Grapes, although not much room is devoted to them; I think not more than three houses. Peaches and Nectarines are much more largely found, the back walls of some of the cooler plant houses being so utilised, and there are great crops on *Early Admirable*, *Grosse Mignonne*, *Dymond*, and other Peaches; and *Early Rivers* (very fine), *Violet Hâtive*, *Pineapple*, and *Lord Napier Nectarines*. Some good bush Figs in pots are fruiting well, and merit a special house. Strawberries, chiefly *Royal Sovereign*, are good, so also are several varieties of Melons. Outdoors there is a large variety of Strawberries blooming profusely. Tomatoes, exclusively *Hepper's Goliath*, the plants 14 inches apart, in a wood trough 13 inches by 6 inches, standing on the stage close to the front, from a January sowing, have covered the roof and are loaded with fruit, a great portion being ripe. It is indeed a wonderful cropper.

In the open there is fair, though not exceeding promise on Apples and Pears, but Plums are thin, whilst *Morello Cherries* are wonderfully abundant. Bush fruits are not heavy crops, but *Red Currants*, as *gridiron* cordons on walls, are crowded with fruit, although the mammoth, which is probably *Red Cherry*, is practically a failure. *Cordon Goose-*

berries on walls and fences are wonderfully good also, indeed they are a marked success.

Vegetables everywhere are excellent. I should have referred earlier to Sweet Peas, which are largely grown in long boxes 6 inches wide and deep, being raised under glass, then put outdoors and staked. The tallest were the other day from 5 to 6 feet in height, and just about to bloom, others following in succession. With the roots so restricted for room, yet frequently fed with liquid manure, Sweet Peas in this way bloom finely for a long season.—A. D.

DWARF AND RUNNER KIDNEY BEANS.

A GOOD succession of Kidney Beans is indispensable in most kitchen gardens. Both Dwarf and Runner Beans require sowing in the early part of May in order to secure plants that will crop freely at the earliest period. Later sowings may be made during June, these proving useful when the early crops are becoming exhausted and there is a demand for nothing but the tenderest pods, which it should be the aim of the cultivator to supply. Dwarf French Beans should be sown every fortnight until early in July. They come quicker into bearing, but also go out sooner than Runner Beans, therefore the advantage of sowing successional will be apparent.

There are other reasons, too, why one sowing only should not be relied upon. A cold wet period may prevent germination or give a check to the young plants after they have advanced above the soil. Enemies in the shape of slugs and snails may devour them, or a sudden frost cripple them past recovery. Some cultivators take the precaution of sowing Runner Beans in boxes and planting out. This is a commendable plan in cold and late districts. Dwarf and Runner Beans require a considerable amount of heat, hence we rarely see good results from very early sowings outdoors, or before the beginning of May.

French Beans ought to be sown 4 inches apart in drills 3 inches deep and 18 inches to 2 feet asunder. The seedlings may be finally thinned to 12 inches apart should the soil be suitable and the season favourable. Failure to crop often results from the injurious crowding of the plants. When the seedlings can be distinguished above the soil loosen the top crust of the ground about them and carry out the first thinning. As growth proceeds and very dry, hot weather sets in, a mulching down each side of the rows will help to retain moisture, but water freely also during continued dry weather, especially in light soil. Stimulants may be given when pods form, but not before.

The bearing capabilities of the Beans may be prolonged by carefully gathering all the pods as they become large enough. If allowed to become old and stringy the pods rob the plants of much support, while at the same time they are useless for edible purposes. Runner Beans may be sown in single or double rows, 5 to 8 feet distance between the rows. Accord similar treatment as for Dwarfs in the early stages, but before the plants begin to twine, the stakes for their support must be fixed. Smooth, straight, well-pointed sticks about 7 or 8 feet long are the best. To double rows a line of sticks must be fixed to each row. The upper ends of the sticks may be drawn together, crossed, and firmly secured.

If sown in single rows the line of sticks may be placed upright, and braced together with suitable horizontal lengths run along the centre, the whole finally made secure with a few very strong stakes driven down diagonally. Tie with strong cord or pliable wire. It is important that the sticks be made very firm before the bine takes possession, as it would be difficult afterwards to do this, and in the meantime strong winds might blow the whole of them down.

Mulch the plants in dry weather, so that as much moisture as possible will be conserved. If necessary to water, apply copious soakings only. The most important time when adequate moisture in the soil is required is when the plants are showing their first blooms. Carefully gather the pods as they become ready, nothing being gained by allowing mature pods to hang on the plants. When the height of the stakes is reached the plants ought to be topped; topping, however, being less necessary with long sticks than with short stakes 3 or 4 feet high.—E. D. S.

PERTH, WEST AUSTRALIA. — By a letter from this township of a far distant colony, we learn that on the 27th of April last the first Chrysanthemum show there was held. The writer states that "not more than sixty blooms were exhibited, and out of that number only about twelve or so were worth looking at. Still it is a beginning, and in an out-of-the-way place like this any improvement is acceptable." No doubt readers of the *Journal* will smile at the suggestion of sixty blooms being regarded as a "show." It is a rather smaller beginning than we are accustomed to in Old England, but knowing how marvellously towns in the colonies develop, Perth, having made a start, may in a few years have a big Chrysanthemum show. Then the writer refers to prices charged for fruit, which seem to us, especially that we get at this time of the year Australian Apples so cheap and good, as somewhat high. Possibly out there the consumers in the populous towns and European countries get all the best, whilst the local people are left without. "Fruit is as dear as ever. Apples from 6d. to 1s. per lb., Grapes 1s. 6d. ditto, Pears 1s. 4d. ditto, Apricots 2d. each, Peaches not purchasable, Potatoes £24 per ton. There is a fortune here for gardeners and fruit growers. If I understood it I should go in for it. Land is dirt cheap, even good; 160 acres can be had for the asking, or at a nominal price." Here is an opportunity for some of our experienced men who at home are vainly seeking employment. Evidently a little capital and a good deal of energy with practical knowledge will help to build up a fortune in Western Australia, but I am too old to go, and hence remain—AN ENGLANDER.

PIMELEA ELEGANS.

MOST of the Pimeleas are useful greenhouse plants, easily grown, free flowering, and of graceful habit, all recommendations of great value. *Pimelea elegans* (fig. 91) is one of the most distinct species, and is deservedly a favourite with many cultivators, as its large heads of creamy white, or occasionally nearly pure white flowers, are produced so abundantly that the plant is ornamental in no ordinary degree. Small specimens in 60 or 48-size pots flower very freely, and this is an especially useful character, as such plants are always in request for conservatory and greenhouse decoration. A moderately light compost of turfy loam and peat with a little sand is most suitable for this as well as the majority of other Pimeleas, and with good drainage water can be supplied liberally whilst growth is advancing. It flowers during the spring months and continues for a considerable time. *Pimelea elegans* is propagated by cuttings of the young shoots, inserting them in moist sand.

FIG. 91.—PIMELEA ELEGANS.

under a bell-glass, and subsequently repotting into the compost previously recommended. The woodcut represents a small branch with a flower of about the natural size. This we trust will be of service to others as well as to "Journeyman."

THE YOUNG GARDENERS' DOMAIN.

THYRSACANTHUS RUTILANS.

THYRSACANTHUS *rutilans* is a stove plant. Few gardeners grow it successfully, and on that account, I believe, it is neglected. It belongs to the order Acanthaceae, and is a native of New Grenada. It is extremely useful for table decoration. The bright scarlet flowers are borne on long drooping spikes, which are produced in midwinter. The plant is worthy of more attention than is usually bestowed upon it. The plants which have come under my notice in several places have been miserable, with a few leaves on the top of lanky stems, looking half starved, and infested with some insect pest, the reason, I think, being that the plants had been subjected to much more heat than was necessary.

When well grown *Thyrsacanthus rutilans* is one of our most charming plants, and is effective in any position. It requires to be grown under much cooler treatment than is usually given to stove plants. It will then make strong healthy growth with leaves down to the pot, and consequently resist much easier the ravages of insect pests.

Well chosen cuttings inserted in small pots about the beginning of

May, root freely in a moderately heated propagating frame. Care must be taken to shade them from bright sunshine, as if they droop at all it checks them considerably, besides helping to destroy the lower foliage. When well rooted the young plants should be shifted into large or small 60's, and when well established gradually hardened, and placed in a house or pit with a temperature of about 55°. After they have well filled their pots with roots, give a final shift into 5 or 6-inch pots, according to the size most useful to the individual grower. They should not be allowed to become root-bound before this is done, as it will cause them to start into flower before they are required.

After the final pots have become full of roots liberal supplies of water are required, and a little soot given occasionally improves the appearance of the foliage. The compost I have seen employed successfully was a mixture of good loam, leaf soil, and well decomposed manure in equal proportion, with a free sprinkling of sand. If the plants are grown for table decoration it is advisable to stop them twice during the season: if, on the other hand, they are intended for ornamenting the conservatory or flower house, they will be found more useful if allowed to grow naturally.—S. S.

THE KITCHEN GARDEN.

"SEMPER," on page 378, April 28th, writes under the above heading, and displays a lamentable conception of the utility of so important a section of horticultural practice—that of outdoor vegetable and fruit culture. Woe for the future fame of British gardeners if all had "Semper's" contracted experience. Does he intend to hug the glass houses till, by age, he deems himself fit for head-gardenship? Scotch lads would feel somewhat insulted if his article applied to them, but happily it cannot.

Scotch gardeners enjoy the reputation of being the best in the world, and the reason must now be apparent to Southerners. Young Scotch gardeners are practically trained in the outdoor section of garden work, plus experience in glass houses. If it were otherwise they would feel like tradesmen who have but half learned their business.

How confined must be the views and reasonings of purely glass house gardeners. Note what "Semper" says:—"By taking a turn round the garden each evening we shall obtain a thorough insight into kitchen gardening." "Thorough!" Could we be masons or joiners worthy of the name by each evening making inspection of a day's work? What of soil surface dustings, which are raked in previous to seed sowing, as preventives of insect attacks? In laying Box edging, what of the methods in securing proper levels and reforming inequalities? Perhaps the opportunity may not have occurred whereby such men as "Semper" could obtain experience in this department, but "where there's a will there's a way." Our faith in the chances of women gardeners is now strengthened.—A YOUNG SCOT.

TO "T. P." AND FELLOW CRAFTSMEN.

As one of the gold penmen, I wish to thank "T. P." and others for their congratulations, of which I have received many. I need hardly say how much I prize the pen, and the Editor's letter accompanying it. "T. P.'s" observations respecting the unsuccessful contributors, and his review of young men's work and studies, have set me thinking. I agree with him that recreation is necessary, but let us be moderate. If we are as eager to rise at 4 A.M. to thin Grapes as some young fellows are for a morning swim, no harm will be done. I have no patience with those who excuse themselves because they cannot write a short article on gardening. If they cannot do this, they cannot write a letter properly, and men who cannot do this in these days are lightly regarded. They should learn.

I am well aware that in many places work is heavy, and the young gardener finds little leisure. I also believe—with that worthy contributor, Mr. D. Buchanan—in the old adage, "Where's there's a will there's a way." There are many I daresay who contribute to the "Domain" at a greater disadvantage than those "T. P." mentions. I am acquainted with one who not only works hard all day, but is to be seen doing anything that is pressing in his own time. This young gardener has the bothy to keep clean and cook his food in his own time, and yet he finds time for the creditable use of the pen. It is not surprising that he gets through so much work, for his motto is "Dogged." Men who can write an intelligent letter, and who are not afraid of work, but who glory in it, no matter of what kind, are the men to make their mark in gardening, not those who are adepts at picking a "winner" or scoring a "century."

We are constantly hearing about men who by sheer hard work, perseverance, and strict attention to duty gain for themselves good and responsible positions. Why not let us follow their example? First of all have an aim. Resolve to do our duty, and work hard and well. Never heed the sluggards and dandies who may poke fun at us. We have ourselves to blame if we do not pass them in the race of life. Dogged perseverance will sooner or later win for us a coveted position. Let us not worry if we do not receive praise for our work, but be content if no complaints are made. Read all we can relating to our calling. Make copious notes on anything that may be useful later on. Be methodical. "One thing at a time, and that done well, is a very good maxim, as many can tell." During periods of pressure let us be the first to offer to work overtime. If we have a real love for our work no task will seem hard, but pleasurable. Let us show that gardening is not likely to "decay," through the next generation being wanting in energy or intelligence.

And now a word to intending and unsuccessful contributors. Follow the rules laid down for "Domain" writers in every particular. They will be found in the *Journal of Horticulture*, December 31st, 1896. A copy can be had for 3½d., and every young gardener should obtain and preserve

it. Keep your MS. clean. Express yourself in the simplest language possible. Do not be discouraged if you cannot write an article straight off, but write and rewrite, revise and re-arrange until you are satisfied it is creditable. Keep a copy of all MS. sent in, so that if you have made mistakes you will then see how to avoid them in your ensuing composition.—NIL DESPERANDUM.

[Very good counsel, but it should be remembered that some contributions are shortened, not because of imperfections, but to adapt them to available space. At the same time, some free penmen are prone to indulge in a redundancy of words. The "rules" alluded to should be carefully studied.]

GO AHEAD, BOYS!

I HAVE been inspired to write a few words to the "Domain," and if my attempt is a poor one I shall, no doubt, have a chance to improve. In my opinion, men who constantly strive for excellence, educationally and professionally, are the most likely to reach the "top of the tree" in gardening. Of course some must fail, but that only teaches others a lesson. Go ahead, boys! and leave no stone unturned to attain the height of your ambition. Do not be disheartened by the wails of some who have not done so well as we would wish. Take my advice, keep going ahead, and if you fail, then you will have the consolation of having done your duty; if you hang back because of so-called poor prospects you are sure to fail. Some are pining because our old aristocracy are not so well able to keep up gardens as formerly; but I venture to think the merchant princes of Britain are more than making amends for the unfortunate falling off indicated. Neither premiums nor examinations will exterminate the "go-ahead" man; he usually comes to stay.—J. G. W.

UNSUITABLE COMMUNICATIONS.

WHILE generally the contributions to this column are highly creditable to the writers of them, we still receive several that cannot be inserted. Those written on both sides of the paper are wholly inadmissible, while some are too closely written for revision, including one from "Multum in Parvo." The writer of the only letter we have in hand from North Wales must not take it amiss on being informed that he has chosen a subject which very few experienced men can treat satisfactorily, and it will be better for himself and others if he confine himself to records of experience in practical work. It is difficult to find room for articles in this column which exceed 500 words. It would be mutually advantageous if our promising young scribes would as nearly as possible follow the advice that is given in our issue of December 31st, 1896. See the remarks of "Nil Desperandum."

HARDY FRUIT GARDEN.

Outdoor Figs.—Attend to Figs growing freely, disposing new growths thinly, and rubbing or cutting off those shoots which are superfluous, owing to want of space. Shoots are laid in now with a view to their bearing fruit next season. If well exposed to light and air the leaves will have a good chance of doing their work, and the wood must become gradually matured. The growths of this season's bearing shoots must be allowed to extend several leaves beyond the fruits before stopping. The current year's wood requires no stopping, but abundance of space to develop. Growth starting from old wood in various parts of the trees are not usually required for laying in, being of a coarse sappy character. They ought to be rubbed off early if they appear.

Strawberries.—One of the best stimulants for Strawberries at the present time is liquid manure, applying it round the plants over the mulching, which it is assumed has been placed between the rows of all fruiting plants. The production of runners must be regulated, thinning out the weakest, and preventing overcrowding, especially if it is necessary to propagate new stock shortly. All the runners should be removed from young plants which are not fruiting this season.

Currants.—Red and White Currants have grown sufficiently, so that the side shoots may be stopped at the third joint. The operation will reduce the foliage and admit light and air, benefiting the basal buds as well as the developing racemes of fruit. Currants appreciate mulchings of rich manure and frequent soakings of sewage when a liberal crop is hanging, as the roots are actively appropriating food from the soil. Black Currants are best left alone as regards pruning, but a mulch over the roots and liquid nourishment are of great benefit to the fruit.

Plums and Cherries.—Vacant spaces, if any, should be filled with vigorous young growths laid in at full length. Superfluous foreright shoots may be shortened at the third full-sized leaf, this encouraging the formation of spurs. As the growths of young trees extend, lay in the shoots at the required distance, but avoid overcrowding. Insects may be kept in check by frequent syringing, either with clear water forcibly applied with the syringe or garden engine, or a prepared solution of soft-soap, quassia chips, or Gishurst compound. Severe attacks of aphides often indicate that the soil about the roots is not in a moist condition.

Apricots, Peaches, and Nectarines.—Continue to lay in successional shoots, selected from the base of the fruiting wood or other suitable

positions. Allow a continuation of growth above the fruit on bearing shoots to attract sap thereto, but pinch at the third leaf, and resulting growths afterwards at the first leaf. Foreright shoots, which are neither well placed for laying in nor desirable to retain to form spurs by shortening to the third leaf, may be cut out entirely.

Outdoor Vines.—Reduce the number of shoots for which room is not available. Some eyes push two growths; one must be discarded, choosing the weaker, or that which is fruitless. Also remove any others which may be unsuitably placed. Shoots which have advanced in length must be carefully tied in position. Stop all that are ready two joints beyond the bunches of fruit. Bare spaces may be filled by allowing suitable growths to extend until the limit is reached, when they should be stopped. Pinch the resulting growths at the first leaf. Allow only one bunch on each shoot.

Gooseberries and Currants on Walls—When trained on walls or trellises as upright cordons the side growths will require to be pinched back to two pairs of leaves, and as soon as the lower pairs have attained full size; the operation may be carried out at short intervals. Where the number of growths is likely to cause overcrowding the weakest may be cut out, including those growing towards the wall. If the cordons have not reached the limit of space, train in the leading growths at full length.

Should the soil become dry, as it is likely to do at the base of walls, a copious watering will act beneficially, not only in affording assistance to the fruit swelling, but in preventing the attacks of insects, red spider being prevalent in many instances, also green and black fly. Following the applications of clear water liquid manure may be freely used to well-cropped trees. A liberal mulching of some material, preferably manure, over the roots, will greatly assist in retaining the moisture, rendering watering less frequently necessary.

Training Newly Planted Trees.—Under favourable conditions newly planted trees will now make new wood freely. With those on walls the growths must be regulated and secured as they extend, giving each branch and shoot liberal space. Trees and bushes in the open require attention more in the way of cutting out unsuitable growths, so that the best situated may have full scope to develop. Gross shoots should be rubbed or cut out, only retaining wood of medium strength for permanent furnishing.

FRUIT FORCING.

Figs.—*Early Forced Trees.*—When the first crops are gathered generous treatment will be needed to enable the trees to swell the second. Syringe twice a day to keep red spider in check, and afford liquid manure when watering is necessary. The second crop should be thinned before the fruit is the size of Walnuts, and in doing so reserve the largest fruits at the base of the shoots. Mulch trees in pots with rich material.

Succession Houses.—When the fruit commences ripening a free circulation of warm dry air should be afforded, which is essential to high quality, not less so being the tying-in and regulating of the shoots by thinning and stopping, so as to afford the fruit the benefit of all the light possible. The moisture in the atmosphere will need to be moderated, not wetting the fruit.

Young Trees in Pots for Next Year's Early Forcing.—The trees must not be neglected, or disappointment is inevitable. They must have all the light possible, and be kept as near the glass as practicable without touching, so as to secure sturdy, well-ripened growths, keeping these clean by syringing. The growth being completed the trees may be stood outdoors to induce rest, but the wood must be well ripened previously.

Peaches and Nectarines.—*Earliest House.*—When the fruit is all gathered from individual trees, the wood on which it has been produced should be cut away to the shoot at the base, which is to afford the bearing wood for next season. All growths not absolutely necessary for bearing next season, or for the extension of the trees, must be removed, as it is important the foliage be fully exposed to light and air. Employ the syringe freely, keep the inside borders well watered, and the outside border must not be neglected if the weather be dry. Admit all the air possible, and when the buds are plump, and the wood thoroughly ripened, the roof-lights, where movable, may be taken off.

Trees Ripening their Fruit.—Syringing must cease directly the fruit commences to soften for ripening. Do not allow the soil to become dry, but supply water as required. A mulching of short spent material is very useful in preventing the surface cracking and the roots going down in quest of moisture. Ventilate freely, leaving a little air on constantly, and to insure the preservation of the foliage in good health sprinkle the paths, borders, and similar surfaces in the morning and afternoon. Some netting suspended beneath the trees is useful to prevent falling fruits being bruised. In gathering the fruit great care is necessary, as slight pressure is sufficient to spoil the appearance. Gather fruit for packing before it is quite ripe.

Trees Swelling their Fruit.—After the fruit has stoned, and takes the last swelling, give every attention to the trees in watering with liquid manure, or, when the soil is moist, supply a fertilising top-dressing. A mulching of short spent manure will keep the surface moist and encourage the roots there. The shoots should be allowed to extend, not pinching the laterals in too closely, but they must be prevented shading the fruit, which should be raised with its apex to the fullest light.

Continue forcible syringings in the morning and afternoon until the fruit begins ripening, but never allow the border and other surfaces to become parchingly dry. The foregoing applies to trees that have been brought forward gently since January, and in consequence will ripen their fruit a month later than those started at the same time and brought forward as rapidly as is consistent with ripening their crops.

Trees started in January.—The fruit having made satisfactory progress is now stoning, having attained a good size. To continue the fruit in steady progress and insure its stoning satisfactorily there must be no deficiency of moisture at the roots, and the foliage must be kept clean by daily syringings. Continue the temperature at 60° to 65° artificially, with a free circulation of air allowed between 70° and 75°, having it full when the latter is reached, and close at 75°, with plenty of atmospheric moisture. If the temperature rise to 80° or 85° it will not do any harm, but admit a little air after nightfall, so as to allow pent-up moisture to escape, and the temperature to gradually cool through the night. Commence increasing the ventilation with the advancing heat from 65°.

Late Houses.—If it is desired to retard the fruit in any of these, it is best effected by a freer and more lengthened ventilation during the day and even at night when mild. It is necessary not to overburden the trees with more fruit in the early stages of growth than can remain for the crop, therefore thin well, but judiciously. Keep the trees well syringed, and mulch lightly, so as to keep the surface moist, giving thorough applications of water when necessary, and if the trees are weak or heavily burdened with fruit afford top-dressings or liquid manure.

THE BEE-KEEPER.

THE WEATHER.

THE past month has not been favourable for bee-keeping. The many changes and the low temperature, which on several occasions kept the bees confined to their hive, have been against them. There were twenty-one rainy days, and 2.21 inches rainfall was registered. The present outlook is dull and gloomy, and with the advent of June cold showers of sleet, hail, and rain are of frequent occurrence; a low temperature, too, prevents the bees obtaining sufficient for their daily requirements.

It is therefore not surprising to hear of various stocks actually dying from starvation. A bee-keeper, who keeps numerous stocks of bees in straw skeps, says, "During the past few weeks I have lost five stocks of bees. During early spring they appeared to be strong in bees, and as the winter had been mild no further notice was taken of them, but after being confined to their hives for a few days I observed a great number of live bees on the floor board so weak that they were unable to crawl back into their hive. On turning up the skeps I found the remaining bees all in the same state, and absolutely without food." We advised hot bricks to be placed round the skep, and the whole covered up warm; the bees would then cluster into the combs, be sprinkled with thin warm syrup, which they would at once take, and if fed regularly would eventually develop into a strong colony. The above came under our personal inspection, and illustrates the necessity of keeping all stocks supplied with stores during inclement weather, at whatever season it may come.

PREPARING FOR A SURPLUS.

It is impossible to predict with any degree of certainty as to the amount of surplus likely to be obtained during the coming season; but whether little or much is secured, the same preparations have to be made beforehand. It is from fruit trees, field Beans, and field flowers we generally obtain our first surplus of honey, and as, has been so often explained, unless the stocks are strong and crowded with bees, there will be only sufficient stored for their daily requirements. But if the colonies intended for honey production are full to overflowing with bees they will store a surplus on the first favourable occasion. This fact should always be kept in mind, and it is encouraging to receive confirmation of what is being done in various parts of the country by readers of the *Journal*. One writes, "All my stocks are strong and in capital condition, and something will have to be done to prevent them swarming; and as I do not wish to make any increase in numbers I am getting my supers ready, which will all be placed on the hives before the middle of the month. As there is such a wealth of flowers in all directions I anticipate an early crop of honey." As the writer of the above resides in an early district we hope his anticipations will be realised.

ENLARGING THE BROOD NEST.

The state of the weather and the condition of the stocks must be taken into consideration before the brood nest is interfered with. If the weather is warm and there is a prospect of its continuing, an extra frame of fully drawn out comb or foundation may be given them in advance of their requirements. The bees will at once commence cleaning it out. If the combs have been used before, or if the foundation be new, the cells will be drawn out in readiness for brood or honey.

During hot weather the bees will gradually spread themselves over the combs. In some extra large hives we have in use, in which there are several combs placed behind the division board, the bees will be found on all favourable days busy cleaning away the debris, and other-

wise preparing them for future use. Keep all weak colonies limited for room, so as to maintain the temperature of the hive as much as possible. The brood nest may be enlarged as often as necessary, but it is as well to err on the side of safety until a favourable change in the weather sets in.—AN ENGLISH BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Fisher, Son, & Sibray, Ltd., Handsworth, Sheffield. — *Bedding and Border Plants.*

H. Henkel, Darmstadt. — *Aquatic Plants.*

W. Mauger & Son, Guernsey. — *Wholesale Bulb Catalogue.*

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Heating Small Greenhouses (F. G.).—We presume you desire to heat the greenhouse, and render it suitable for the growth of plants in winter without the aid of a boiler and hot-water pipes for distributing heat throughout the house. We do not know of any oil stove that we should trust to do this in a house of ours of the dimensions you give. If you turn to advertisements over a few back numbers you will find small borders for heating far more reliable than a stove inside the house.

Sewage Farms (P. W.).—We do not know of a book on the "management of sewage farms." If any of our readers can recommend one which they have found useful, and will favour with its title, price, and publisher, we will gladly furnish you with the information. We received the communication you sent some time ago, but doubt if its publication would serve any useful purpose. Similar suggestions have been published more than once or twice, and the discussions that followed had no practical result; your letter, however, is still in existence.

Muscat of Alexandria Grapes Blackened (A. W.).—The berries are simply shanked. No doubt keeping the house too close and moist would aggravate the evil, but the defect arises chiefly from an unsuitable rooting medium. The border may be too close and wet, or deficient in suitable nutrients, or an excess of something prejudicial. In such cases a dressing of lime frequently has a good effect. We should give this in conjunction with soot, using equal parts by measure, and employing half a pound of the mixture per square yard, point in very lightly. The lime should be best chalk lime, air slaked, or slaked with the least amount of water necessary to cause it to fall into a fine, apparently dry, floury condition, and cool when used.

New Coreopsis (H. D.).—If you had seen the flowers on their arrival their pitiable condition would have brought tears into your eyes. Four flowers, loosely placed in a dry box, without any packing, large enough to have held 200, were so dashed to and fro in transit that there was really very little left of them. We could see they were larger than other shrivelled and shrunken Coreopsis flowers would have been, and of a rich orange in colour. We presume they were cut from a plant that was raised from seed in the autumn. We should think that such flowers when fresh would be generally acceptable at this period of the year. If they had been so closely packed in soft green grass as to have been immovable they would no doubt have arrived in excellent condition. See our remarks below, under "Names of Plants."

Seedling Gloxinia (Rheola).—The flower, so far as we can judge from its shrunken condition, was no doubt when fresh bright and attractive, lobes scarlet margined with white, and a spotted throat. The variety is worthy of increase for home decoration, but we doubt if it is of commercial value. You took great pains in packing, but in the wrong direction. See our remarks on the subject in the above lines.

Hibiscus sinensis—Maple Leaves—Magnolias (J. C. S.).—Hibiscus rosa-sinensis and its varieties are stove plants, but are sometimes grown in a warm greenhouse, the soil being kept dry in the winter, but not allowing the wood to shrivel. The sprays are not those of Acer saccharinum, for the leaves of this are "cordate, smooth, palmately five-lobed; lobes acuminate, sinuately toothed." There is no toothing on the lobes of your specimen. It appears to be A. palmatum, or a form of it. Magnolia glauca has white, very fragrant flowers in May to July, and is a very fine evergreen shrub. M. obovata discolor, syn. M. purpurea, is a pretty, small, deciduous shrub with flowers purple outside and white within, and fragrant. M. fuscata is a greenhouse evergreen shrub with dull purple, very fragrant, small flowers. The two first named are hardy, but the first is best grown against a wall in cold districts.

Pear Leaves Diseased (R. D.).—The cause of the insects in the Pear leaves we do not know, other than that they find in them the food essential to their existence and continuation. The insect causing the blisters is the Pear leaf mite, Phytomyces pyri, which spring from eggs deposited in the tissue of the young leaves, and when the mites are developed they pass through an opening in the under side of the leaf to other leaves, biting through the outer skin and causing a blister, in which more eggs are deposited in turn in the gall, and so on till late summer, when males and females are developed, these living dormant in the scales of the buds during the winter. The best cure is to prevent the enemy attacking the trees in spring by dressing the buds carefully with petroleum emulsion, diluting the kind advertised with six parts of water, and applying in winter with a brush or spray distributor. You may also now use the emulsion, diluting according to the instructions, on the under side of the leaves, by spraying upwards. This will deter the mites spreading to other leaves.

Diseased Melon Shoots (J. L. M.).—The leaves had the appearance of attack by the Cucumber mildew, Plasmopora cubensis, but under culture the diseased parts have developed fruits of the common mould, Pencillium glaucum, usually associated with decayed organic matter. We found no trace of any other micro-organism, nor was there anything to account for the browning, or rather scorching, of the points of the shoots and young leaves. We have known such to arise from excessive evaporation on bright weather recurring after a period of dull and cold, the plants not being in very good condition at the roots, or too dry. The symptoms are not inconsistent with an attack by eelworm at the roots, but of that we can offer no opinion. There has been a sudden check of some kind, but by what caused we are unable to say in the absence of any information to guide us. The plants affected may recover if the disaster has been caused as suggested, the conditions of growth are as favourable as possible. In most cases, however, stunted plants seldom prove satisfactory. If eelworms are present you will find the roots knotted or swollen, in which case uproot, scald the soil, and plant anew.

Vine Leaves Brown and Sickly (M. D.).—The leaves have every appearance of being attacked by red spider, but they are, as you say, "very clean" in that respect, and there is no trace of insect infection. The younger leaves have the upper surface freckled by yellowish brown spots with yellow centres and reddish borders, with numerous yellowish pustules on the under side of the leaf. On the older or fully developed leaves the spots have reddish borders, the leaf assuming a brown appearance as if mature, but with a sickly and dried-up aspect. The under side of these leaves is covered with numerous small black pimples, and from these issue a very curious thick thread from the apex of each, which twists about in a horn-like manner, and consists of threads of bodies glued together by an adherent substance. The minute pimples on the young leaves are the early, and those on the older foliage the matured pustules or pycnidia of the black rot fungus of the Vine, Lœstadia Bidwelli. The berries show no trace of the parasite, but the disease does not appear upon them until about a fortnight after the spores mature on the leaves, and we are pleased to find they are not very active in germination, and may not develop on the cuticle of the Grapes, as they, being in the ripening stage, may have too tough and hard a skin for their penetration. Under the circumstances we should not do more than use a little sulphur on the hot-water pipes, heating them occasionally, say twice a week, to as near the boiling point as possible without actually making the water boil, keeping the house close for about an hour, and then allow the pipes to cool, and after a time admit the usual amount of air at the top of the house. This we consider will prevent the spread of the fungus, for it certainly cannot thrive in a dry and well ventilated atmosphere. Damp is an essential of germination and development, favoured by moisture on the leafage and fruit, such as occurs at night when the house is kept close, and in dull weather when little or no air is given. When the leaves fall or those attacked become useless burn them, including all damaged fruit, so as to get rid of the resting-spore stage of the fungus, and in winter dress the rods with a 10 per cent. solution of sulphate of iron, applying with a brush, also remove the surface soil of the border inside, and use an ounce of the sulphate per square yard as a top-dressing, and leave it there. Follow in the spring with best chalk lime, half a pound per square yard, and leave it on the surface to be washed in.

Roses in Pots (P. N.).—How far you may be able to satisfy your desire time only can reveal. We will, in an early issue, point out how they may be raised without the aid of glass, but fear you will consider the process rather slow.

Bedding Plants for a Dry Position (Amateur).—Zonal Pelargoniums are the most effective in fairly good soil and open positions. Heliotropes, Ageratums, Iresines, Coleuses, Golden Pyrethrum, Lobelias, and the various annuals raised under glass, all thrive well in a medium soil, and the bulk of them will stand drought fairly well after they are once well established. Petunias are suitable for quite the driest beds, and Marguerites may be associated with them advantageously. Dwarf Nasturtiums, if grown on rather poor soil and given good room, are remarkably showy, and stand both wet and dry weather well. If the beds are in a very dry state when they are to be filled give them a good watering a few hours in advance of planting, and the work can then be done easily and properly.

Increasing Marguerites (M. M.).—You will find that suitable cuttings can be rooted in June, as well without a greenhouse or frame as with those conveniences. Procure a box, such as a starch box, and bore a few holes in it for drainage, or rather to prevent stagnation of the soil, place a crock or oystershell over each aperture, then half fill the box with light sandy soil, pressing it down firmly, and cover the surface with pure sand. Next give a thorough watering through a fine-rosed can, and then, not before, choose, make and insert the cuttings. Growths, not too soft, but certainly not hard, without any flower buds are the best. They may be about 3 inches long or a little more, and two-thirds of their length divested of leaves, the end of each cutting being cut smoothly across with a sharp knife, not torn by a blunt one nor bruised by a pair of scissors. Insert the cuttings up to the leaves, making them firm by pressing the soil against the lower part of the stem with a pointed stick, and mind each cutting rests firmly on the soil, and is not suspended in a hole made too deep for it. Give a sprinkling to settle the sand about them, then lay glass across the box. The tops of the cuttings should be about an inch below the glass, which must fit closely for excluding air. Stand the box in a shaded place either outdoors or in a frame, but not under trees, and few of the cuttings will fail to grow. We should not expect to lose one out of a hundred. When they grow and touch the glass tilt it a little to admit air, and if the leaves do not flag admit more and more air till the plants will endure full exposure and sun. They will then be ready for placing singly in 3-inch pots, and if they can be kept close in a similar manner to that advised, in a deeper box, they will be established the sooner. When fairly growing they may be fully exposed, and when roots protrude through the drainage shift the plants into 5-inch pots for flowering, potting firmly in good loamy soil. They make excellent growth in the open air in summer much better than in a window, but the pots should be stood on ashes or other base impervious to worms, and, of course, the plants must be judiciously watered throughout, regulating supplies by the growth and the weather.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. W.).—1, *Cratægus pinnatifida*; 2, *Cercis siliquastrum* (the Judas Tree); 3, *Cratægus tanacetifolia*; 4, *Amelanchier canadensis*. (R. F.).—1, *Aërides Fieldingi*; 2, a good form of *Cattleya Mossiæ*; 3, *Cypripedium Lawrenceanum*. (B. P. S.).—1, *Pyrus aria*; 2, *Prunus (Cerasus) padus*. (A. L. G.).—1, *Saxifraga aizoon*; 2, *S. trifurcata*; 3, *S. hypnoides*; 4, *Thalictrum aquilegifolium*. (P. I. F.).—1, *Hemerocallis flava*; 2, *Corydalis lutea*; 3, *Philadelphus floribundus*; 4, *Geranium pratense*; 5, *Veronica gentianoides*; 6, an *Aquilegia*, species not determinable without flowers.

FRIEND OR FOE?

A NAME often reveals a good deal of the habits or character of the possessor. This is especially so with regard to the scientific appellations given to members of the animal and vegetable world; in fact, as a rule some distinctive feature is made prominent by the name. "*Corvus frugilegus*" is very full of meaning, especially to us, who provide the corn for the gatherer—corn that we meant for ourselves, not for the maw of the black coated rook. We consider at present we can look upon the rook dispassionately, or at least we feel disposed to take a lenient view of his misdeeds.

A rookery in the garden is a very pleasant adjunct to a country house. Observation of the habits and the gentle murmur of the never ceasing "caw caw" are very soothing and pleasant. True, the rooks are very untidy builders, and have no notion of tidy ways when Saturday comes; the mere human must then remove all the litter of broken sticks and miscellaneous rubbish which accumulates so rapidly; and the rooks are desperately keen on hens' eggs. This is when the young are hatched. We have often watched an old crow hovering round and about the stick heaps in a large poultry yard, and seen the egg fresh laid deliberately carried off—indeed, we have detected stolen nests by observing the attention paid to that part of an overgrown fence by the black marauder.

Who knows that country delicacy, so common in May—a rook pie? tender and juicy, and with, to our mind, much more flavour than a pigeon pie. We read so much of the evil deeds of this bird, that we are inclined to wonder if we do wrong by encouraging and fostering him year after year; and we have come to the conclusion that it is possible to encourage too much—that a multiplication of

rookeries is a mistake, like the over-preservation of game. In districts where the rook is much in evidence, it stands to reason he falls short of natural insect food, and must, to preserve life, have recourse to that which he has neither sown nor reaped.

We hear, too, in some neighbourhoods that no pains are taken to keep the birds properly thinned down; it is so easy a business in May to do so, that for the interest of the farmer it should never be neglected. Most owners of large rookeries organise shooting parties, and give a great deal of pleasure to young folks—for after a certain time in life we old people see no fun in craning our necks and spending hours in damp plantations.

What is it the rook steals? His enemies say everything that he can carry. Last autumn we had a field of late-sown Wheat after Potatoes, and the rooks were always thereabouts. The weather was very dry, and Wheat came up slowly, and despite a tenting boy we feared the seed must have been much molested. There were places all over the field where the land was scratched and regularly worked about, as though all the hens on the place had been dusting. However, the crop came up well, with no apparent shortage, and we believe now the rooks were more intent on the few remaining Potatoes than on the grain. He is a destructive bird in a field of newly set Potatoes, and has also a nice taste for the new ones as soon as they are formed; possibly he is on the look-out for wireworms, and the Potato is such a temptation—too strong to be resisted.

It has been said that a rook knows by instinct at which Swede root lies a wireworm, and that he never digs up any but an infested plant. That may be so of an old bird, but what of the youngsters that are learning their business—do they never make a mistake? We cannot help fancying they do, and the Swedes are the innocent sufferers. We have seen a freshly hoed and singled piece of Swedes devastated in one afternoon.

What about standing corn? Is the rook always innocent? Is it the wood pigeon alone who does the damage? Witnesses aver they have seen Master Rook fly off with ears of corn, which he enjoys quietly by himself in some adjacent pasture, and in some neighbourhoods where he is over-preserved he becomes very bold, and will actually draw out the ears of corn from the stack side.

In very severe weather visit a Swede field near the haunt of rooks, and see how the roots are pitted and marked and mangled by the iron bill, leaving the remainder to speedy decay.

Following the plough in spring, there is no more valuable bird than the rook. He requires at least 1 lb. per week of food, and as long as that food is principally wireworms, crane fly, and beetles we are his grateful friends, but when after the Barley is drilled he is afield again we do not feel so justified in defending him.

Early in March we heard of a rook being shot, and the contents of his crop were 200 grubs and one Oat. In May we further read of a rook's crop which contained 100 Barley grains and no insects. Does not this rather point to the fact that as soon as there is grain about the rook prefers it to grubs and worms? We think the bodies of a few dead rooks either attached to sticks or laid with outspread wings on the new sown corn are a way out of the difficulty, and a wary hand, spite of all that is said, can always manage to "down" a few old crows for the purpose.

We ourselves thoroughly believe in dressing corn with coal tar before sowing. A pint of tar carefully mixed with half a gallon of hot water till the tar is dissolved, then more cold added, sprinkled over the heap of corn, and this well turned about, will prove a deterrent to rooks or any other birds. This quantity of mixture will dress 4 bushels. Of course where rooks have been so encouraged as to become a perfect pest a raid should be made on rookeries at breeding time—that is, if permission can be obtained.

Never have we personally been overrun with these birds, but we can quite enter into the feelings of those farmers whose crops are constantly ravaged, and we know unless the owners of rookeries will co-operate the case for the farmer is almost hopeless.

[We wonder if our correspondent's dog would eat his "rook pie delicacy." We have known a man with a generally good appetite refuse it because, as he said, "hungry dogs would not touch it." Is this so?]

WORK ON THE HOME FARM.

More rain and cold weather! Work will soon be in a backward state, for we can seldom take horses on the land with any prospect of doing useful work. Already we have lost all the advantage gained by a most favourable winter.

We keep all hands at work with the hoe, but weeds kill badly and spring corn hardly grows at all; there can be little hope of Barley being ready to cut in August, and this crop now looks worse than we can ever recollect. Oats are nearly as bad. Wheat stands the cold fairly well, and being forward and strong may come to harvest by mid-August; it is quite the best crop of the year.

Potatoes are well up in rows, and we are keeping the horse-hoe hard at work whenever the land is sufficiently dry, but we have to be careful, for horses' feet do much harm amongst Potatoes when the land is wet. There will be none to earth up yet awhile. A few were tinged brown with frost one night, but there has been no material injury, and we hope that frost is done with for the present.

We are applying sulphate of ammonia to the late Potatoes now at the rate of from 1 to 2 cwt. per acre according as we think the crop will pay for it. To the second earlies we are giving nitrate of soda, as being quicker in its action. Care must be taken only to sow these manures when the haulm is quite dry; a heavy dew will sometimes be enough to prevent sowing till the afternoon.

It is time to drill Swedes, but much too cold and wet for the operation. We must possess our souls in patience and wait for more sunshine. For Turnips to do well the soil should be warm to the hand; the small plants will, under such conditions, soon make up for lost time.

If hands can be spared the grass and rubbish should be cut with hooks from the bottoms of hedges recently taken down, or the young growths may be smothered and revival of the fences much delayed. Old sickles are capital instruments for this work.

Mangold must be kept clear of weeds, and as growth is slow this cold season a top-dressing of nitrate of soda will be beneficial, 1 cwt. per acre now, and another after singling.

FARMERS IN CHINA.—The following account of the agricultural population of China, from Rev. James Johnstone's "Story of a Successful Mission" (Hazell, Watson, and Viney), is interesting:—"By far the largest number of the population among whom the missionaries have to work are agricultural—the farmers and farm labourers with their families—all, young and old, being less or more engaged in the work of the field. They are generally poor, but are, on the whole, a healthy, honest, kindly and most industrious and frugal race. . . . In Chinese society the farmer stands second in the social scale, next to the scholar in point of respectability, and the scholar stands next to the Emperor. . . . What makes the Chinese farmer, even the smallest, a self-respecting and independent man is that he holds his land by what is practically a permanent tenure. The Emperor is the owner of all the land in that vast empire, larger than the whole of Europe—the largest landowner in the world. The farmer of a few acres who holds his farm by direct title from the Emperor, if his title is what is called a red title—that is, not a transferred one—cannot be legally deprived of his land so long as he pays the rent. Even if he is obliged to part with his lease from failure of payment, like the Jews of old, he or his heirs can claim it back any time within thirty years, if he or they can pay the back rents with ordinary interest thereon. The rents are not high, for the average quality of land the price is about 6s. per acre per annum, inferior kinds can be had for 1s. or 2s. the acre, and the best for 8s. or 10s."

REMARKS.

29th.—Generally cloudy, but occasional sunshine; rain from 11 P.M.

30th.—Rainy till 4 A.M.; sunny at times in morning; frequent drizzle after 3 P.M.

31st.—Alternate sunshine, cloud, and storm rains; hail at 11.15 A.M., and thunder in afternoon; cloudless night.

1st.—Sunny early; occasional sunshine and frequent heavy showers during the day.

2nd.—Dull, gloomy, and showery morning; frequent sun in afternoon, but thunder at 2.45 and 3.43 P.M., and storm rains at 11.30 A.M. and 4 P.M.

3rd.—Brilliant early, and sunny morning; generally cloudy after noon.

4th.—Generally overcast, but a little sun in late afternoon.

An average week, with rather more rain than for some months past.—

G. J. SYMONS.

W. CLIBRAN & SON'S DESCRIPTIVE CATALOGUE OF Garden & Conservatory Plants.

Replete with invaluable information, is sent post free to any address on application. Buyers are invited to inspect the magnificent representative collections of every class of these plants at the **OLDFIELD NURSERIES, ALTRINCHAM**. To those who cannot come the fullest information as to price, sizes, &c., will be sent on request.

HERBACEOUS, ALPINE, AQUATIC, AND BOG PLANTS.

Of these alone the stock numbers several hundred thousand plants, all of the very best procurable types.

COLLECTIONS (our Selection only):—12 sorts for hot dry situations on Rockery, Walls, &c., 4/-; 12 for moist shady Rockeries, 4/-; 12 for sunny borders, 4/- and 6/-; 6 Aquatic plants for deep water, 6/-; 12 Aquatics for boggy places, 4/- and 6/-; Asters (Michaelmas Daisies), 6 sorts for 2/6, 12 for 4/-, 25 for 7/6; Sempervivums, 12 sorts from 3/6; 50 fine showy Border perennials in 50 varieties, 15/- and 21/-; 100 ditto, in 100 varieties, 35/- and 42/-. As all these plants are supplied in pots, they may be planted out practically at any time.

HARDY CLIMBERS FOR OUTDOORS.

(Our Selection.) Clematis, 12 fine sorts from 10/6; Ivies (finest green and variegated varieties), Honeysuckles, Wistarias, self-clinging and other Virginian Creepers, Ceanothus, Menispermum, Aristolochia, 12 fine sorts in pots, 12/-.

CLIMBERS FOR GREENHOUSE AND CONSERVATORY,

Including Passion Flowers in great variety. Stephanotis (the freest blooming form), Clerodendron Balfouri, Lapageria (finest varieties), and many others at 10/- and 30/- per dozen and upwards, according to size.

STOVE AND GREENHOUSE PLANTS, FERNS, &c.

12 varieties flowering Stove Plants from 10/-; 12 varieties foliage Stove Plants from 18/-; 12 varieties Greenhouse Plants from 12/6; 12 varieties Caladiums from 12/-; 12 varieties Crotons from 24/-; 6 Epiphyllums from 7/6; 12 distinct named Gloxinias from 18/-; 12 Streptocarpus seedlings, in 3 inch pots, from 6/-; 12 double seedling Begonias, finest selected, true to colour and shade, 12/- to 30/-; 12 distinct Ferns for stove from 9/-; 12 ditto for Greenhouse from 6/-; 12 different Adiantums from 6/-; seedling Ferns for Rockeries, Table Decoration, &c., from 3/- per dozen.

DOUBLE CACTUS DAHLIAS.

SPECIAL OFFER.—12 splendid Cactus Dahlias, including the following superb Novelties of 1897:—Cycle, Ensign, Flossie, Harry Stredwick, and Mrs. Kingsley Foster, together with Beatrice, George Marlow, J. E. Frewer, Lady Penzance, Mrs. Wilson Noble, Mrs. Francis Fell, and Viscount Boyne. Post free, 12/6.

Clibrans, Altrincham & Manchester

CHRYSANTHEMUM GROWING FOR EXHIBITION.

Mr. W. MEASE, Gardener to A. TATE, Esq., Downside, Leatherhead, July 3rd, 1897, wrote—

"I used your special CHRYSANTHEMUM MANURE last year with very satisfactory results, having won the Two Jubilee Gold Medals at the Aquarium for Cut Blooms." And again in November, he adds—"Your Manure is invaluable for finishing off Chrysanthemums."

The above is prepared from the receipt of
J. J. WILLIS, of Harpenden.

Sold in Bags—1 cwt., 17/6; 56 lbs., 10/-; 28 lbs., 6/-.
Sample Bags, 14 lbs., 4/- Carriage Paid to any Station in the Kingdom.

WILLIS BROS.,

Manure Specialists, HARPENDEN, HERTS.
List of other Manures on application.

CARNATIONS!

Mr. WEGUELIN'S CATALOGUE for 1898 comprises the Latest Novelties & Choicest Exhibition Varieties in cultivation. Sent Gratis on application to—
H. W. WEGUELIN, F.R.H.S.,
ST. MARY CHURCH, TORQUAY.

TOKYO NURSERIES CO.

—HEADQUARTERS FOR
Japan Lilies, Cycas Revoluta
Morning Glory,
and all kinds of Japanese
Plants, Seeds, &c., &c.
Large Assortment always in
Stock.
Orders promptly executed.

KOMAGOME, TOKYO (JAPAN).
Cable Address—"Nurseries, Tokyo."

LONDON FERN NURSERIES,

LOUGHBOROUGH JUNCTION, LONDON, S.W.—Ferns, large and small, in variety; Aralias, Grevilleas, Cyperus, Ficus, Ericas, Palms, Dracaenas, Aspidistras, Hydrangeas, Pelargoniums, Fuchsias, Marguerites, Crotons, &c. Trade, send for Wholesale List. Special List for Amateurs, send for one.—J. E. SMITH.

CACTUS DAHLIAS. Best Plants
Best Varieties.
Moderate Prices.
Catalogues, with full particulars, gratis on application
KEYNES, WILLIAMS & CO.,
The Nurseries, SALISBURY.

30,000 PTERIS TREMULA, in thumb pots, and 20,000 Pteris Cristata, in thumb pots, at 12/- per doz. boxes of 15 in each; also Sweet Peas, Princess Beatrice, pink and white and blue, in thumb pots, at 15/- per doz. boxes of 15 in each; also Nasturtium, dwarf Tom Thumb, dark red, in thumb pots, at 15/- per doz. boxes of 15 in each. Free on rail for cash with order.—H. PESTER, Enfield Highway.

NOTICE.—Don't stake your Carnations till you have seen the Patent Improved Coil Stake. No tying required; stakes last a lifetime. The greatest boon ever offered to growers. Only wants seeing. 7/6 per 100; sample dozen, 1/-, carriage paid. Cash with order.—A. PORTER, Stone House, Maidstone.

DEFY THE BIRDS by Buying our Noted **ROTLESS TANNED NETTING**, as supplied to the Principal Gardeners in the Kingdom. Orders over 5/- value are sent Carriage Paid. 100 yds. by 1 yd., 3/-; 200 yds. by 1 yd., 6/-; 300 yds. by 1 yd., 9/-. Can supply any length and width.—**UNIVERSAL SUPPLY ASSOCIATION**, East Street Works, Reading. (Name Paper.)

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—**HIRST, BROOKE & HIRST, Ltd., Leeds.**

PROFITABLE FRUIT GROWING FOR COTTAGERS and SMALL HOLDERS of LAND. The Gold Medal Prize Essay. By J. WRIGHT. Written for the Worshipful Company of Fruiterers. Demy 8vo, price 1/-; free by post, 1/3.—**JOURNAL OF HORTICULTURE** Office, 12, Mitre Court Chambers, Fleet Street, E.C.

GARDEN NETTING, small mesh, keep out the smallest birds, oiled and dressed; will not rot if left out in all weathers. 105 yds. by 1 yd. wide, 3/-; by 2 yds. wide, 6/-; 105 by 3 yds. wide, 9/-, and so on to any width; carriage paid on all orders over 5/-. As supplied to the Royal Gardens. Commoner netting, 50 square yds. for 1/-. I do not require Payment until you have received and approved of the Netting.—From H. J. GASSON, Garden Netting Works, Rye.

GREENHOUSES from £3 5/-; **VINERIES**, **CONSERVATORIES**, **FRAMES**, **SUMMER HOUSES**, &c. Illustrated List Free. Makers to H.M. THE QUEEN and H.R.H. THE PRINCE OF WALES.

READING. (Name Paper.)

Journal of Horticulture.

THURSDAY, JUNE 16, 1898.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St. London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

"HOT AND COLD."

IT has more than once been urged on the attention of writers for the press, or those young men who desire to become such, that when there is a choice between long and grandiloquent terms on the one hand, and short and simple words on the other, for the expression of an idea, a safe rule to follow is to choose the shorter. As with the pen, so with the voice, those who convey their thoughts with the least apparent effort, and are content to employ the short, smooth words of their mother tongue, are those who best make themselves understood. There are, of course, some short words that are not "smooth," and these may be eschewed as useless, in favour of the useful and agreeable.

Then in the transaction of business, the nature of it suggests abbreviation, and even total changes of words, which are employed as a matter of convenience, and well understood by those immediately interested. This is so in connection with the production and sale of various kinds of garden produce, as in the trio of simplicities which for the first time form a not inexpressive headline in the *Journal of Horticulture*, but they have nothing to do with the weather outside nor temperatures under glass, and have no connection with heated argument or cold criticism. They have just the same significance as "Cues" and "Toms" and "Roons," no more and no less, which stand as denominating factors in the trade vocabulary in which Cucumbers, Tomatoes, and Mushrooms are the products in question. Thus is effected a saving of letters and of time—of the former by just half, or from twenty-six to thirteen, while the shortened symbols trip lightly off the tongue, whereas the words complete and in combination represent somewhat of a mouthful. This would surely be felt to be so if uttered several times a minute for an hour, during the process of auction or other sales. It is precisely the same with "Hot and Cold."

"But what crop or crops can these possibly stand for?" many persons might not unnaturally ask, who had nothing to guide them to the comprehension. They really stand for two very familiar

crops to most people, but of greater importance to those who grow them extensively and well than the majority understand. Represented in their scientific form we should have *Sinapis alba* and *Lepidium sapidum*, but this would never do; it would be too overwhelming and decidedly better is the popular rendering, Mustard and Cress. And now that the secret is out it may be wonderingly asked, "If any simpler terms can possibly be needed?" Test the matter for yourselves, ye who may thus wonder, by shouting "Mustard and Cress" fifty times as fast as you can, and perhaps your tongue and thorax will be glad of a rest; do the same with "Hot and Cold," and the organs will be in as good going condition as ever. Or take another test; write the words down an equal number of times, and you will find you have used just twice the amount of ink, time, and space over the repetition of one formula as the other, so it will be seen that the making of simple terms simpler still has its uses.

Even now all that is pertinent has not been said. It can be proved that "Hot and Cold" is a more correct term to employ than "Mustard and Cress" in the industry in question—more exact, truer and safer, while certainly not less expressive. But how more exact and especially "safer?" Well, if a trade grower sold 100 gross of Mustard and Cress for £60, which would be about the wholesale value, and were driven to resort to an action at law to compel payment, he might happen to lose the case on a technical point, for the defendant could put in the plea that half the "stuff" sold was not as represented in the invoice; but no such risk could be incurred if the goods were sold under the recognised term of "Hot and Cold," for that is precisely what they are.

Another point now arises. Suppose all the readers of these lines had a punnet of this commercial Mustard and another of Cress before them as supplied to and obtained from Covent Garden, and votes were taken as to which was the "Hot" and which the "Cold" in the opinion of the members of that great jury. Would they all be alike, and all correct? It is questionable. In a small test the majority of those who gave their opinion quickly and without much thought was in this form:—"Why, Mustard is 'Hot' of course." Those who reflected were not quite so sure, as they could not say that tongue-biting Cress is "Cold." It is wise to "think" before voting on anything if you wish to be right, as it is so easy to be wrong in a headlong rush.

Those who thought over the subject the longest were right in this particular case, for the Cress is the "Hot" and the Mustard the "Cold" of the great purveyors for the London market, whence millions of neatly packed punnets pass to all the popular centres in the kingdom. As a matter of fact, as many persons know, the punnets of "Cold" and sold under that term, are a dense mass of young, smooth, silvery stemmed Rape plants; and, as many more persons do not know, if the punnets were packed with young genuine Mustard plants they would not sell half so freely, nor realise perhaps half the price.

It is useless forcing on the market for meeting the wants of the million produce that has nothing beyond what a connoisseur may regard as "quality" to recommend it. Tempting appearance appeals far more powerfully to the great bulk of purchasers than does anything else. If they will not have the woolly, dingy-looking stemmed Mustard, let them have the pure glassy-looking stemmed Rape for contrasting with the dark, thick, succulent young seed leaves. It is the same in respect to other products. That which "looks" the best, and especially early in the season, sells the best, even the showy International Potato, which its raiser, Mr. R. Fenn, declared was not good enough for pigs. He declined to put it into commerce, though it found its way there, for more money to be made by it, because it gives heavy crops of large tubers in good time, than he ever made by his other varieties that possessed his high ideals of quality. Well, all honour to the man whose desire to increase the flavour and food value of a staple product was greater than his thirst for gold. "Question!" Yes, the digression is ended, with apologies. The question is "Hot and Cold," and the story about to begin. "Begin! Oh! better say finish." Please do not be impatient; the infliction will not last long.

Six or seven years ago some lectures on gardening were given under the auspices of the County Council in a certain corner of Surrey. About that time an eminent scientist, and excellent man, published as his opinion that gardening could not be taught in lectures. Well, not being a gardener, he thought so, but did not know. It has been taught in various aspects almost ever since at the meetings of the Royal Horticultural Society, and the lessons published in the Society's journal. But let that pass. Attending the lectures in a Surrey workman's club was a cottager who loved his garden and allotment, and took prizes at the local show. Among the subjects which most arrested Mr. W. Newton's attention were Cucumbers, Tomatoes, and Mushrooms, and it was mentioned that the remains of the Mushroom ridges formed the best possible material for the growth of Mustard and Cress. It was on the main subjects, however, on

which he asked the most questions, and was told not to cease till he felt he understood the various details as elucidated by the aid of diagrams. He proceeded till he was able to say, "I now feel my feet, and will have a try."

To decide by such an earnest man was to act. Wood and glass were obtained forthwith, and he filled his long back garden with two span-roofed houses, the work of his hands. One he devoted to Cucumbers, the other to Tomatoes. He had seen none grown, but worked entirely from the winter instructions, and no one seeing the houses the following summer could but have admitted that the work in them in all cultural details equalled that of a trained gardener. The end of it was that within a year of his club-room lessons, he sold the produce of his well applied labour and skill for more than £200. Good for a cottager whose daily labour was among bricks and mortar.

When such a man starts in such a way, so long as he has health, he is not likely to stop. Mr. Newton, with his healthy frame, clear head, strong arm, and persevering labour, went on. How many capacious span-roof structures he has now on his own freehold cannot be remembered, but there are many, forming an imposing block. In these are grown Cucumbers in summer, and "Hot and Cold" in winter, as well and as profitably as these crops could be produced, not the least satisfactory being the winter produce. Tomatoes are only now grown to a limited extent. The surrounding soil is low lying, no doubt a reclaimed swamp, and quite black with vegetable matter. It is therefore not adapted for "Toms," so "Cues" are mainly relied on as the summer crop.

The "Hot and Cold" culture is by no means limited to the houses in winter and early spring. The zealous grower secured all the land he could in an adjacent allotment ground for Mushroom ridges, and after gathering heavy crops from them, utilising the then decayed manure in a large area of improvised frames, a great extent of these covered with sashes, others, as warmer weather approached, with mats or other material. As a matter of routine, however, stretches of newly sown seed are first covered with mats, usually a double, if not sometimes a treble thickness, spread directly on it. As growth proceeds they are gradually withdrawn, and when the plants are an inch or so high the last is removed, and lights, liberated by previous cuttings from a similar area, placed over for finishing the crop. The work thus goes on with machine-like regularity, and a great and wonderful work it is for a man whose days were spent in handling bricks and mortar to have accomplished in so short a time.

As a general indication of the scope of his operations in the growing and selling of "Hot and Cold," it may be said that the output is 120 gross of well-filled punnets a week, or more than three-quarters of a million a year—or, to be a little more precise, 898,560, worth, at the wholesale price, £3744, though a large local trade is done by heavy purchases, for the Croydon market particularly, which caters for not less than 150,000 people, and for such sales by the five or ten dozen punnets to many purchasers, materially higher prices are easily obtained. The London consignments average 100 boxes of five dozen punnets thrice a week during the busy season, or 18,000, weekly value £75.

The punnets are packed in two tiers, but with nothing whatever between them, those constituting the upper tier standing directly on the produce in the lower without injuring it in the least, or it would not be done. This demonstrates how closely and firmly the 6000 "cuttings" at a time are packed in the punnets. The work is done well and done quickly—an art only to be acquired by experience. It may seem strange to those who have not seen the process that a man will cut and pack faultlessly thirty dozen punnets in an hour, or six a minute, and maintain the pace for eight or nine hours. As a matter of fact the two men told off to the work must do it to have ready the bi-daily demand.

It is due to them to say that they appear to do it easily, and without the least apparent bustle; indeed, one old hand, on being spoken to on the subject in a complimentary way, remarked, like the spider of old, in a "come into the parlour" sort of way, as he thought he saw a fly, "If you would like to venture a sovereign against forty dozen, I am ready to oblige. The fly was not caught. He had seen too many wily old spiders. It is a treat all the same to see smart, educated workmen, because it is only by "educated" eyes and hands that such feats of skill, for skill it is, can be accomplished.

As may be imagined, a considerable outlay is involved in the conduct of the operations, in the form of labour, seeds, punnets, and general routine, but there is the happy pendant that the greater the outlay the better for all concerned—master and men. The capital now employed simply represents the fruits of the work of previous years, and these only a few. To begin with, the resources of the "master" were not in his pocket, but his character, his enterprise, prudence, good judgment, and unflagging industry. Step by step on wisely judged, firm, sure ground, he has won all that is to be seen, and a great deal more.

Fancy a man who was at "day-work" seven years ago making a present to the public of £15 worth of punnets a week all the year round. During the busy period—March-June—his weekly punnet

bill ranges from £21 to £22; all these thousands of chip punnets being given away for the purpose of selling the produce in them. Then there is the seed. The last order given was for 50 quarters of Cress, and 75 quarters of Rape—not an ounce of Mustard. To insure the best English Rape a stock is provided a year in advance. The market has been known in previous years to be drained of the best home samples, and recourse had to foreign seed. This did not satisfy. The best seed obtainable gives the best produce of "Hot and Cold," and the best profits to the grower. Some £300 to £400 may be resting in sacks of seed at the present moment, but a germinating time will be certain to come of seeds and money, with the result of a sure and profitable harvest—ready for cutting in five days from sowing.

The last named fact is significant, for it simply means that a greater number of crops of "Hot and Cold" can be obtained from any given site in a given time than can be had from any other product in existence, whether grown in Cucumber or other houses in winter and early spring, or between planks on edge and the space bridged over by moveable sashes, or other screens, in the open, after the houses are wanted for summer work. Every one of these crops, well grown and well packed, or, in other words, of the first class in bulk and in quality, leaves a good profit behind it; and it follows that a working man who obtains fifty-two crops a year, and sells 17,000 to 18,000 punnets a week, deriving 20 per cent., perhaps more, on the outlay has not made himself a very bad business.

"How are these quick successional crops produced?" Brains constitute the chief factor. They have told the grower that every weekly crop of "Hot and Cold" must have an entirely fresh rooting medium. They have also told him how to provide a sufficient bulk, and it is a large one, of the very best kind for nothing—or rather at a sufficient profit to pay for the labour incurred in its preparation and use. It is in this way. Manure is bought, prepared, and formed into ridges, spawned, soiled, and covered, and a greater profit is obtained from the resulting Mushrooms than could be derived from any other edible product that could be raised on the same site, except perhaps "Hot and Cold," and this could not be had so well without the refuse from the Mushroom ridges.

This is wheeled into a large heap, and after a rest all that will pass between the wires is rushed with shovels through a large slanting riddle. The shorter of the fluffy portion that will not pass through is used as a bed, 2 or 3 inches thick, evenly pressed down, on which is spread a layer about 2 inches thick of the sifted decayed manure, smoothed, surfaced with a film of cocoa-nut fibre refuse, or preferably cedar refuse—a local product resulting from pencil-making—watered, sown, matted, kept moist and dark; the previously soaked seed starts into growth at once, the mats are by degrees removed, one good watering given, and the crop is ready within a week when the warmth is sufficient for its growth.

It is a close, dense, level mass, with not a particle of husk, grit, or anything else on the verdant surface. So thick is the sowing and dense the growth, that punnets can be thrown on it with impunity to be handy for the cutter. In a moment his keen, angled knife (fig. 92), with a push and a draw or two, severs the stems, seldom one too many or too few at a time, the portion severed

FIG. 92.—SMALL SALAD CUTTER.

not falling; it is seized with both hands, and with a turn of the wrists is wedged in the punnet (fig. 93) in one deft quick movement. It is emphatically skilled labour, and the men are properly paid the average wages of good gardeners.

Lads supply the cutters with empty punnets, and the packers with full ones. Men with barrows follow the cutters, and take out in flakes the material placed in a week ago. It bristles with short stems, and is matted closely with myriads of roots. It is heaped for the vegetable matter to decay, turned over, and in a year is ready for use again, the remains of one crop affording appropriate food for another, and so the round of work and rest, of life and death, and life again goes on—a great lesson in a small way on the marvellous economy of Nature, whatever more.

It is not infrequently advised that Cress seed, because of the comparatively slow growth of the plants, should be sown a day or two in advance of Mustard, so that both may be ready at the same time. In the larger culture under notice all the seed is soaked for twelve hours. The Rape seed just swells, but takes up little water. The Cress seed during the same time absorbs its own weight of water, swelling from 1 bushel into 2 bushels in a day or a night. After being left to drain a little it is rubbed through with dry sand, as if separating Carrot seed, sifted, and sown with the Rape (which

is not so treated), and both crops are ready for cutting at the same time.

This story of a worker, however incomplete, has extended to greater length than was expected. It may, perhaps, however, be tolerated. The narrative is not without interest; it should be encouraging, and may possibly be useful. Be that as it may, such progress by a son of toil, who has made himself in so short a time the second largest grower of "Hot and Cold," so far as is known, in the world, is worthy of recognition in the *Journal of Horticulture*.

FIG. 93.—CHIP PUNNETS.

A small portion of the work described is shown in the illustration (fig. 95, page 503).

Another branch of Mr. Newton's outdoor culture, in part on land of his own (the best part), in part held on a rental of £50 an acre, may be referred to in a future issue. In the meantime, those who happen to think the rent a little high may perhaps wonder and guess what the crop can be that pays it—and the grower, too.

SPRING TRENCHING AND ITS RESULTS.

I WOULD like to say a few words in answer to Mr. Pea's paragraph in your issue of June the 9th. Mr. Pea will persist in "confounding things that differ." He says his experience has been disastrous for my arguments. I might have left this unnoticed, for your correspondent "Examiner" gives answer sufficient to both the experience and arguments of both Mr. Pea and Mr. Dunn.

My remarks were based on my experience under entirely different circumstances to those under which my able literary opponent practises. He, no doubt, correctly relates his experience. Does he suppose my observations for the last sixty years are not correctly related? He is a man, we will hope, with a long happy future before him, and may regard the remarks of one well through his eighth decade as visionary. He has persistently ignored the conditions under which I found spring digging more desirable than that of autumn. If Mr. Pea had ever practised on a heavy soil, where I sometimes experienced 25 inches of rain in two consecutive winter months, I venture to think that he would have found it impossible to alter either the philosophy or the results that I have advanced. He seems to try the impossible and question my results. I judge his remarks more charitably as to his practice in dry Kent. I presume if he was placed on a similar soil to that I originally referred to, and where I sometimes registered nearly 6 feet of rain in twelve months, I feel pretty sure he would fall into my practice. On the other hand, if I had to deal with his clay I would take a very different method of improving it, with permanent results, by practices adopted in some cases perhaps before Mr. Pea was born, or at least ever handled spade or fork.

It was the wet climate of Drumlanrig that I wrote of, and nearly thirty years' practice there confirmed the correctness of my methods. The soil there now is permanently very different to what I found it. I have old pupils practising in Kent who could tell that I found a large part of the kitchen garden a strong yellow clay, from which the bricks of the surrounding walls were made. I did not do the amelioration as I did 6 acres of strong yellow clay in Middlesex by burning it; the climate of Drumlanrig in winter would have drowned out the burning process.

It was by wheeling on to the clay quarters great quantities of old Vine borders and other light materials, such as the finest sittings of ashes and a great amount of soot out of the flue I had constructed to take the smoke of the furnaces three-quarters of a mile away from the garden. Anyone who sees the height the quarters are above the walks at this date can form an idea of the amount of light material put on them. If I were Mr. Pea I would not, in a dry climate like Kent, be long bothered with such a pasty mass as he describes. If I could get coals and some old trees to set fire to it, I would burn it, and wheel or cart on it all the light material I could lay my hands on, and then turn all over the same as you would mix soil on a potting bench. Expensive work, some may exclaim. Not half so expensive as the unsatisfactory annual work Mr. Pea describes, as a few years of labour saved and the increased yield would soon put the credit figures on the right side.

As for Mr. Dunn's objections and criticisms, I really do not know

what more to say after what "Examiner" has so pertinently said. It is high time anyone who cannot understand why heat radiates more rapidly from a solid body than from a loose body of soil (resulting in its being the more deeply frozen) furnished himself with some textbook on natural philosophy, at which both your correspondents indulge a partially veiled sneer. A little study of these laws would open up a new world to them in the garden, as well as in most things.—D. THOMSON.

KINGSTON CHRYSANTHEMUM SOCIETY.

I HAVE received a copy of the schedule for the next November show of this Society. It is not an exhilarating document, because it shows a considerable deficit owing to various causes, but this deficit is not representative of any indebtedness to other than the recently appointed Secretary, who, as assistant to the late Secretary and Collector, has so far foregone any payments due to him for two years. Very material reductions have also been made on the previous year's classes, the Committee being very anxious to keep expenses well within their probable income. It is pleasant, however, to find that the show will this year be held on the 1st and 2nd of November, and will not thus clash with the National Society's show. It is hoped that for such reason some of our leading trade growers and others desirous of assisting the old Kingston Show will send some fine exhibits, for only a determined effort is needed to place this once leading Society on a more satisfactory basis.—A. D.

SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE June meeting was held in the Society's room at the Museum Hotel on Wednesday, the 8th inst., when Mr. M. H. Willford, Secretary of the Walkley Floral Society, read an essay on the "Amateur's Orchid," when he fully explained his method and treatment of the Orchids which he thought most suitable for amateurs. It was an excellent treatise, and was fully appreciated by the members present. He exhibited a fine spike of *Lælia purpurata*, and a spike of an *Oncidium* bearing a profusion of neat blossoms, notwithstanding the formidable specific title of *Phymatochilum* which was attached to it. Amongst the best kinds he recommended for amateurs were *Odontoglossum Rossi majus*, *O. maculatum*, *O. crispum*; *Oncidium crispum*, *O. varicosum* Rogersi, *O. flexuosum*; *Cypripedium insigne*; *Cattleya labiata*, Mossiæ, and Trianæ; *Lælia purpurata*, *grandis*, and *anceps*; *Dendrobium nobile* and *Wardianum*; and *Miltonia spectabilis*.

The monthly exhibits were table plants for amateurs when Mr. Willford secured first, Mr. W. Donaldson second, and Mr. W. Willgoose third prizes; and *Gloxinias* for professionals, Mr. C. Scott obtaining first and Mr. J. Dixon second prizes, no third prizes in this class being awarded. After a good discussion on Orchids, the essayist and the Chairman (Mr. J. G. Newsham) were each awarded a vote of thanks.

CURRENT WORK AMONG CHRYSANTHEMUMS.

THE final potting of Chrysanthemums will now be proceeding rapidly—in fact, completed by many growers when these notes appear; but there are doubtless others who, through pressure of important work in the garden, have been compelled to defer the operation for a time. Little or nothing is gained by very early potting, provided the roots have not become impoverished in the 32-sized pots. To obviate this I advocate the application of perfectly clear well-diluted soot water, both at the roots and foliage—to the latter of course by syringing, which should always be done in the evening. This gives the plants tone without unduly stimulating them into rank growth, while it acts as a deterrent of insects. But though over-luxuriance must be averted at this season of the year, a little manurial assistance is often beneficial before the final potting, as aiding the plants to lay a sound foundation, always remembering that uniform unchecked growth is essential from the cutting pot to the final shift.

By potting and standing the Chrysanthemums out of doors at an early date the cultivator runs great risk of serious damage being sustained by gales of wind and hail. These were prevalent last month, and gave a decided check to exposed plants, from which, unless the weather be of the most favourable character, they will be long in recovering. It is highly desirable where convenient to keep the plants in frames, or where they can be sheltered with glass as desired until the first week in June. Abundance of air can be afforded them by raising the frames on bricks, and keeping the lights off day and night during mild settled weather.

The compost, pots, and stakes, indeed all requisites, should in the meantime be prepared so that the potting may be completed with dispatch, and the plants forthwith arranged in the position they are to occupy for the remainder of the summer and early autumn. It is important that the soil in the smaller pots, and that to be used in the larger, be suitably moist—neither too wet nor too dry—and also that the new be pressed down as firmly as the old. Assiduous care must be exercised in watering. If the soil at potting time be fairly moist no water will be required for two or three days. The state of the weather at the time will guide the cultivator in this essential point. Frequent syringings will be absolutely necessary throughout the first week if the

weather be dry, always using water which has had the chill taken from it by the action of the sun's rays, and if rain water be procurable so much the better. As soon as it is seen that the plants have taken a firm hold of the new soil weekly syringings with soot water will greatly benefit the plants, as will soon be seen by the intense green hue of the foliage.

Those growers who use the bamboo canes for staking their plants will have made the tops secure from their old enemy the earwig. Nothing forms a safer and surer harbour for this pest than the hollow canes, and these should be either cut off at a joint or plugged. These canes are very much in request for staking, and if the 8-foot black canes be used I know of nothing to surpass them. Hazel stakes are preferable to the white bamboo canes. The latter have fallen into bad repute, and rightly so, for what looks more unsightly than long rows of them along the sides of garden paths? It is necessary to have the tying material of good substance, and to secure the stems very loosely in order that the points of the plants may not become damaged. If they are free to sway somewhat with the wind they will be less likely to snap than if drawn up tightly to the stake. Another important phase in the summer management of the Chrysanthemums is regular and prompt attention in taking out the side growths, which should always be performed cleanly, the evening being the best time for this operation.

Feeding the plants should be commenced as soon as the pots become well filled with roots. For the first few applications I prefer to use weak clear liquid manure only, such as the drainings from the farmyard; or sheep or deer droppings may be collected and placed in a bag, placing this in a tub or tank of water, always allowing it to soak well before using the liquid. The same method should be adopted in preparing soot water. A solution of good guano, as occasionally advertised in the *Journal of Horticulture*, used at a strength of $\frac{1}{2}$ oz. to a gallon of water, is highly beneficial, alternating these with an approved chemical manure, such as Beeson's, Clay's or Thomson's, all of which give substance to growth. Sulphate of ammonia, in dry or liquid form, requires to be used with extreme caution. It is easy to indulge too freely in its use and do much more harm than good, and probably sufficient nitrogen will be given through the agency of the manures enumerated above.—H. T. MARTIN.

ROYAL HORTICULTURAL SOCIETY'S EXAMINATION IN HORTICULTURE, 1898.

WE have received the report of the examiners appointed by the Royal Horticultural Society to test the knowledge of candidates on the subjects embraced in the questions that will be appended. The questions, it may be stated, are not disclosed till the moment comes for answering them. Candidates then choose eight out of the sixteen (four from each division), and make the best of them in the allotted time—2½ hours—without consulting books or notes to aid them in their duties. The report is as follows:—

The annual examination in the principles and practice of horticulture was held on April 6th: 190 candidates presented themselves for examination. Of this number 155 were from all parts of England and eleven from Scotland; nineteen gave no address on their papers.

Three hundred marks (the 360 named was a mistake) were allotted as a maximum, and all candidates who obtained 200 marks and upwards were placed in the first class. The total number was eighty-seven, or 45·7 per cent.

Those who received 150 and less than 200 marks were placed in the second class. The number was sixty-one, or 32·6 per cent.

Those who obtained 100 and upwards were ranked in the third class. The number was thirty-six, or 19·0 per cent.

The highest number of marks was awarded to Miss O. M. Harrison of the Horticultural College, Swanley.

The great advantage of systematic training is seen in the fact that of the pupils—e.g., of the Swanley College, twenty-four were in the first class and only four in the second. Of those of the Technical School of Stafford there were twelve in the first and seven in the second class; of the County School of Horticulture, Chelmsford, eight were in the first class and four in the second; while of the Horticultural School, Holmes Chapel, Cheshire, six were in the first class and four in the second.

Comparing the results with those of last year, we find that the number in the first class has slightly decreased—viz., from eighty-nine to eighty-seven. In the second class there is an increase from fifty-five to sixty-one; and also in the third class from twenty-eight to thirty-six. Those not placed have fallen from twelve to five. Comparing the per-centages they stand as follows:—

	1897 (184).	1898 (190).
First Class...	48·3	45·7
Second Class	29·8	32·6
Third Class	15·2	19·0
Not Classed	6·5	2·6

The answers were, on the whole, very satisfactorily given; and the general standard of those dealing with the elementary principles of vegetable physiology were somewhat better than was the case in 1897.

There is also a general improvement in the answers to questions referring to practical horticulture. Most of the students have a good general idea of the work, although a limited number only went fully into the minor details of it; but some of these details are essential to a full measure of success, and as far as possible they should be included in the answers.

GEORGE HENSLOW, {
JAS. DOUGLAS, } *Examiners.*

Before giving the names of the 184 successful candidates, with the number of marks obtained by each, it may be well to publish the questions on which the examination was founded. These may form useful studies for young gardeners, and answering them as well as they can, as pen and mental exercise, will be instructive and good preparatory work for future examinations in which they may like to participate.

QUESTIONS.

Eight questions only to be answered; four from Division A and four from Division B.

DIVISION A.—ELEMENTARY PRINCIPLES.

1. Describe the methods of propagation of different weeds; explain why Groundsel and Chickweed and the large white-flowered Convolvulus are particularly troublesome. What are the best means of exterminating these plants?

2. Point out the importance to the plants of a good circulation of air in a hothouse, and the consequences of a stagnant condition of the atmosphere within it.

3. Describe the different functions of leaves, and the best way to secure their due performance.

4. What are the component parts of a flower, and of what use are they respectively to the plant?

5. What external conditions are favourable for inducing variations to appear in cultivated plants; and how would you proceed in order to fix any variation?

6. What parts of the flower are retained and altered in forming the fruit of the Peach, Melon, Mulberry, Fir-cone, and Pine Apple?

7. To what natural orders do the following trees belong:—Tulip Tree, Maple, Apricot, Ash, Laburnum, Guelder Rose, Horse Chestnut, Hornbeam, Thuia, and Evergreen Oak? Which are natives of this country?

8. Describe the structure of the bulb of the White Lily, the corm of Gladiolus, the creeping-stem of Couch Grass, the rhizome of the Flag, and the tuber of the Potato; and explain their uses to the plants.

DIVISION B.—PRACTICE.

9. Describe landscape gardening as an art.

10. Describe the formation of a garden lawn, and the details of the work necessary to keep it in condition during the year.

11. What are the preliminary operations necessary to the laying-out of a garden for fruit and vegetable culture? Describe the arrangement of the fruit trees, and the method of planting them.

12. A garden having four walls facing north, south, east, and west, what varieties of fruit trees should be planted on each? Describe their first year's pruning and training.

13. Give full details of the propagation and culture of Grape Vines and Fig trees in pots.

14. Describe the culture of Seakale, Asparagus, and French Beans; and the best method of forcing them.

15. What are the best manures for kitchen and fruit gardens? How ought they to be applied, and when?

16. Describe the propagation and culture of Roses and Carnations intended to be cultivated under glass.

As to the questions, it may be said, though differing every year, they suggest that botanical and scientific, as well as practical cultural knowledge, is requisite for answering the stipulated number satisfactorily. Some of them are intended to encourage study and stimulate research, and may be regarded as tests of the intellectual acquirements of students in the directions indicated. It is not improbable that the marks of many industrious and culturally able gardeners would run low in Division A, while in this section they would run high (as they ought) by students who have the advantage of constant systematic training in technical schools.

Moreover, it may be assumed that the majority of the students in such establishments have had a much better general education than those youths who have passed direct from elementary schools to employment in gardens, and the former, in addition to acquiring special knowledge by coaching, are naturally better equipped than the latter for displaying it in the time and the form required in examinations. That is a powerful factor in their favour. The free and intelligent use of the pen is, and ought to be, an important element in the gardener's education. Gardening, in its highest aspects, is intellectual work, and gardeners should be intellectual men, of literary as well as practical working attainments.

Having seen hundreds of "papers" written in the form of answers to questions on gardening by earnest, worthy, respectable men, we well know the disadvantages under which many of them labour in making clear on paper the sound practical knowledge they undoubtedly possess. The R.H.S. examiners in their report above note the desirability of fuller minor details in answering questions on practical horticulture. Many most capable workers are intimately acquainted with the several details on which success hinges, but do not possess the "pen faculty," so to say, for their representation. We have given some encouragement to young gardeners to improve themselves in this direction, and have not a doubt that some of these will soon be competent to pass with credit through the ordeal of a R.H.S. examination. One to whom a gold pen was awarded is, as a matter of fact, in the "first-class" list of the present "exam."

SUCCESSFUL CANDIDATES.

FIRST CLASS.

	No. of Marks.		No. of Marks.
1. Miss Olive M. Harrison, Swanley ...	285	45. W. J. Hurford, Carshalton ...	225
2. Miss Mary Banks, Stafford ...	280	47. Miss Marion Hawkes, Swanley ...	230
2. O. H. Faulkner, Stafford ...	280	47. William H. Neild, Holmes Chapel ...	230
2. C. Lawrence, Stafford ...	280	47. Miss E. Morland, Kew ...	230
2. Miss Ethel S. Lutley, Swanley ...	280	47. G. W. Pyman, Chelmsford ...	230
2. C. Mann, Stafford ...	280	51. John Benson, Aughton ...	225

Glancing at the list of candidates and their marks, the observations of the examiners on the "great advantage of systematic training" is abundantly justified, for what do we find? Remembering that the maximum number of marks that can be allotted was 300, we find that with only three exceptions the nineteen candidates who obtained 260 and upwards were college or technical school students, and eight of them ladies, while one (Miss Olive M. Harrison, Swanley College) has won the premier position, and may therefore be described, with congratulations, as the Senior Wrangler, with 285 marks. Seven others of the nineteen, who are not more than 60 below the maximum, are Swanley students, while six have been trained in the County Technical School, Stafford, and one each in the Technical Laboratories, Chelmsford, and the Municipal Technical School, Leicester. The three others are Mr. F. A. Gwilliam, Palace Gardens, Gloucester; Mr. A. Tanner, schoolmaster, Cobham, Surrey; and Mr. H. H. Thomas, Kew Road, Surrey; and all are complimented on their success.

Several other students in the institutions mentioned, also in the Horticultural School, Holmes Chapel, Chester, have passed in some of the classes. Altogether we find eighty-five students in the lists from those technical schools, leaving only ninety-nine from the whole of the counties of England, in fact from the United Kingdom, where no special training is given for purposes of examination. We find the names of twenty-two ladies in the lists, all, save one, with the prefix "Miss" (and nearly all from Swanley), the notable exception being Mrs. J. Chapman, Wimbledon Park, and we think the men folk ought to congratulate them on their diligence and success.

Regarding Swanley as cosmopolitan, the college there being open to all the world, and the "Misses" beating the "Mr.'s" out of the field, the county, with no central college or school of horticulture, which heads the list of successful candidates is Surrey, with twenty-three. There appears to be the same number from Staffordshire, but nineteen of these are from the Technical School. Then the fall is great, Berks, Lancashire, and Hants (including the Isle of Wight) coming next in order, none exceeding a dozen. The "Garden Isle," though small, seems to have done nearly as well as Yorkshire, and better than any other county, except those named. Half the counties of England and Wales are not represented, nor is Ireland, though, as the report states, there are eleven students classed from Scotland.

Are the results satisfactory? One thing seems clear—namely, that the progress is not so general as the promoters of these examinations can desire to see. Why is there not a wider increase in the numbers of candidates? One reason is that a very considerable number of gardeners conceive that students in colleges and technical schools should, as such, have a separate examination. Whether this is advisable, and if so practicable, is for others to determine, but we know that some of the most able and intelligent gardeners decline to enter the lists of candidates under the existing conditions, and perhaps they would not enter under any other. They object to the scheme itself, which they regard as tending in the direction of the manufacture of gardeners largely by artificial processes, to the ultimate disappointment of a large number of them who cannot hope to find appointments which they can fill with satisfaction to themselves and others in an already seriously overstocked market.

It is not unreasonable that this feeling should prevail, seeing that so many excellent men cannot find employment in the calling to which they have worked so long and well. Furthermore they will ask, as we have been asked time after time, if the very best gardeners in Britain to-day, or in the world, have been made what they are by paper examinations? It is difficult to meet such questions, and if the examiners can do so we shall be delighted by their aid.

We have no difficulty whatever in answering another familiar question—"Are those persons who obtain the greatest number of marks to be regarded as the most competent all-round practical gardeners?" The reply to this is, "Certainly not; and a number of them never intend to be competitors for employment in the gardening

ranks." We know that this is so, both in the case of ladies and schoolmasters, but these are the better satisfied with themselves, and may be of more service to others by the knowledge they have obtained in an art in which they are interested, and which they believe it would be well for more to understand. In our opinion there cannot be too many persons imbued with such views, for we are convinced that the greater the number of people who are brought to love gardening, and to learn all they can about it, the happier will be their lives, and the better will this aggregate love and knowledge be for the community as a whole.

But there are obviously two kinds of gardening—the higher and more elaborate, and even luxurious, type for the comparatively few—the wealthy; the more plain, useful, attractive in a small way, but not less enjoyable for the many—the workers. For these—small villa residents, artisans, cottagers, and allotment holders who delight in gardening—the teaching and the tests must be different. Some of them, we know, struggle with the R.H.S. questions, but except in the case of a few educated amateurs, hopelessly. They indulge in the idea that by passing an "exam." they will pass into the ranks of professional gardeners, and be eligible to serve in that capacity in the gardens of the wealthy. It is a mere dream. There is better hope for them by starting in a small way commercially, and by degrees establishing a business that may be useful, as some have done. The private gardeners who will always be most in demand are those who are not only well grounded in the theory of the art of horticulture, but who have also gone through the mill of experience in more than one arena of practice—or, in other words, they must be expert physical workers, competent in a multitude of duties, as well as trained directors, whether they be men or women. It is admirable to see the endeavours that are being made to this end; but there is some danger that the outcome of all this zeal may be the production of rather too many superficial gardeners, by the art of coaching and cramming for the winning of marks in pre-arranged examinations—a process that has been tried and found wanting in elementary schools, and hence in most, if not all, of them largely discontinued in favour of surprise visits by inspectors and practical tests in routine work.

PYRUS FLORIBUNDA AND GOLDEN PIPPIN APPLE AS DECORATIVE TREES.

Apropos of the former, or rather of its variety, *atro-sanguinea*, mentioned on page 463, I am reminded of recently seeing several fine specimens in charming array in the pleasant grounds at The Grove, Harborne, the seat of William Kenrick, Esq., M.P. The trees in question are tall standards with densely branched pendulous heads, growing at about 50 yards apart in a long boundary border, enclosing a portion of the grounds from the public roads, the whole of the wide border being well furnished with a variety of other ornamental trees and shrubs, backed with a line of principally Austrian Pines. During the months of May and June, when Lilacs, scarlet and pink Thorns, Brooms, *Berberis Darwini*, *Rhododendrons*, Azaleas, and other similar plants, fronted with groups of hardy herbaceous flowers, unfold their flowers, this belt is very handsome.

Beautiful and attractive, however, as the various forms of *Pyrus Malus floribunda*, including *spectabilis* (the Chinese Crab), their compeers, some of the ordinary Apples, are equally beautiful, and worthily claim a similar position as ornamental trees. Especially does this apply to the old Golden Pippin with its rich deep pink blossoms and semi-pendulous habit of growth, and of which in particular I recently noticed one or two fine old specimens growing amongst several other sorts in a large cottage garden, or rather orchard garden. The scene in question is located at the junction of two public roads forming a partial boundary of a field, and embosomed on the side of the orchard facing the field is a very quaint old-fashioned Ivy-mantled cottage, thus lending enchantment to the view.

Long may this unique beauty spot be permitted to remain, and not—it may be relevant to remark—share the fate of an adjacent old cottage on the opposite side of the road in having been recently razed to the ground for highway improvements. It, too, was mantled with Ivy to the ridge of the roof. Tradition says that a family of Huguenots, when they were banished from France upwards of 300 years ago, found an asylum in this abode, and as a means of maintenance pursued the art of silk weaving. This locality is also additionally rich in historical attributes, inasmuch as within a stone's throw from the two old places adverted to is the residence once occupied by Cox, the celebrated landscape painter, and in the front garden of which is growing a Weeping Willow hanging its branches over the public footway. It is said to have been planted as a slip or cutting from the tree growing over Napoleon's grave at St. Helena. Also along one side of the same road or street are growing several large ornamental-foliaged Thorns, the gift of a French prince when on a visit to the neighbourhood.—W. G.

PEAS AND STRAWBERRIES.—It may interest some readers to know that Green Peas were picked here on the 9th inst. I cannot say the variety, but Harrison's Eclipse on a warm bank is practically ready too. The first unprotected Strawberry ripened on June 6th, a yearling root of Laxton's No. 1, being six to ten days earlier than similarly treated plants of Royal Sovereign and Noble.—EVESHAM GARDENER.

LÆLIO-CATTLEYA INTERMEDIO-FLAVA GOLDEN GEM.

THIS charming bigeneric hybrid was staged at the Temple Show by Messrs. Charlesworth & Co., Heaton, Bradford, and received from the Orchid Committee an award of merit. It is one of the most brilliant in colour that has resulted from the cross. The narrow stout sepals and petals are rich yellow, as is the inner portion of the throat. The front lobe of the lip, which is long, is beautifully fringed, and of a peculiar orange-crimson colour. It is very bright throughout, and the flower is most attractive. It is depicted in the illustration (fig. 94).

IONOPSIS PANICULATA.

ALTHOUGH a very beautiful Orchid this cannot be recommended for general cultivation, and the blossoms to hand from my correspondent, "J. R.," are evidently from plants that have not been long under cultivation. Newly imported masses, both of this and *I. utricularioides*, the only two species grown, move onwards with a fair amount of vigour, and, moreover, produce very fine spikes, but plants in thorough health after say six or eight years in this country, I have never seen, and I am afraid I never shall see.

They flower themselves to death as a matter of fact, the large branching panicles of flowers being altogether out of proportion to the size of the growths, and it is sad to see the little shoots getting weaker and weaker yearly. The best plan to pursue is to wire the plants firmly down to blocks of Tree Fern stem and keep them in a house the atmosphere and temperature of which are not given to fluctuation. Light syringings on warm days are helpful in keeping down insects and maintaining a little moisture in the atmosphere surrounding the plants. *I. paniculata* is a native of Brazil, and was introduced to this country about thirty-five years ago, though long known to botanists.

DENDROBIUM RHODOPTERYGIUM.

In this species, which is not by any means commonly grown, we have a very fine and attractive Orchid. The growth is stout and erect, or nearly so, deciduous, and the flowers are very freely produced, almost from end to end of the rough-looking stems. These occur on two or three-flowered racemes, and are rosy purple on the sepals and petals, often shaded or spotted with white; the lip is brighter in colour.

The culture of this *Dendrobium* is not difficult, and newly imported plants of it especially grow with great vigour. I like to put it well up to the light, and unless a suitable position is at command, should grow it in baskets in preference to pots. The compost will be of the usual peat and moss mixture, and though the newly imported plants are best in receptacles of rather restricted size, when a shift becomes necessary they may have more room. Grow it in the warmest house at command until the last leaf appears on the young stems, then gradually reduce the temperature, but still keep the plant in a good light, and eventually put it in a cool greenhouse. It is a native of Burmah, and was discovered in 1874.—H. R. R.

ORCHIDS ROUND LONDON.—THE WOODLANDS.

JUST a fortnight ago my first visit was paid to The Woodlands, Streatham, the home of Robert H. Measures, Esq., and at the outset it may be well to say that going with high anticipations I returned astonished and delighted with what had been seen. Of course The Woodlands' collection ranks with the finest, but until it had been visited its extent, its excellence, and its completeness had most unquestionably not been grasped. It has become customary in notes of this nature to conclude with a word of thanks to the owner and his gardener, but on this occasion I would reverse the order of things, and thank Mr. Measures for his kind reception, and for the feast that was displayed before my eyes, as well as the gardener, Mr. J. Coles, for the information so cheerfully given. This gentleman differs from most Orchid lovers in not showing his plants—not even send-

ing them to the Royal Horticultural Society for certificates—growing them wholly and solely for his own pleasure and that of his friends, and it can be well imagined that the store of pleasure must be inexhaustible. Day by day fresh flowers will be opening, and if they were not there are still the plants, whose leaves to the lover of them are well nigh as beautiful as the flowers.

Though Mr. Measures has been established in his present home for about eighteen years, it is only about sixteen since Orchid culture was first commenced, the nucleus of the present magnificent collection being some plants of *Cypripedium barbatum* bought at a sale in the neighbourhood. The admiration that was extended to those *Cypripediums* remains to this day, for the collection of Slipper Orchids is one of the finest in the world—if not in size, certainly in quality of the species, hybrids and varieties. Many are unique, and money could not purchase them. Look, too, at the *Lælia elegans*, which are acknowledged as the best in Europe. Every variety that could be was procured, until its present state of excellence was reached, and even now additions are constantly being made from reliable sources. No form of ordinary merit could find a place—all must be above it; then, and then only, can space be found for them at The Woodlands.

It must, however, be distinctly understood that while these two sections are the prime favourites, all other Orchids are represented to a greater or lesser degree. With all, too, the same desire is in evidence to reach a high standard of excellence, and it may be said that the efforts made are successful. House after house is entered, and in all of them are many Orchids in the rudest health. In several structures a departure from orthodox lines has been made, and instead of all having ordinary staging the plants are placed out in compost between large pieces of tufa rock. The effect thus produced is very charming, especially as Ferns, *Sibthorpias*, *Lycopods*, and other plants are utilised as a groundwork. Beneath the stages, too, a successful endeavour has been made to enhance the picture by building up with tufa, and planting Ferns in the crevices between the blocks.

But we must not continue with generalities, or reference will not be made to the several individualities that are worthy of it. The present is not the time of the year to see *Cypripedium insigne* in flower, but the splendid plants are there, and they tell of beauties that have gone, and of glories that are still to come. The collection of *Cypripediums* as a whole numbers between 4000 and 5000 plants, some of which have not yet flowered, while others have flourished for several years. Of the forms of *insigne* we hope to speak in a special note when they are in flower in the autumn, and for the

nonce it must suffice to observe that varieties of the highest merit are abundant. It may be interesting in connection with the insignes to record that in one importation four plants of *C. hirsutissimum* were found, besides several others that are sufficiently distinct to warrant the supposition of their being natural hybrids.

Other species of hybrid *Cypripediums* are now in flower, and many very beautiful forms are observable in the house devoted to them. Several of these are of great beauty, especially such as *Lawreanum*, *Sir Trevor*, and *Mastersianum*. The collection of *bellatulum*, *niveum*, and *leucochilum* is very comprehensive, and this section is especially favoured by Mr. Measures. Of the plants noted were *Annie Measures*, *Hector*, *Mrs. Herbert Measures*, *William Lloyd*, *hybridum Watsonianum*, *Lucianum superbum*, *H. Hannington*, *Monica Measures*, *Faireyanum*, *insigne Measuresæ*, *i. Sanderæ*, with many others, of which, as has been said, we hope to furnish particulars at a later date. That these referred with the remainder will produce an unparalleled display later in the year there can be little doubt, and it will be through no fault of the owner and grower if they fail to do so.

Reverting now to quite a distinct section of the Orchid family, we come to the *Lælia elegans*, and those, unfortunately for the writer, are not now in flower. It was, however, easy to see from the splendid growths, that a rich treat was in store for the late summer months, and it is hoped that we shall be able to examine them at leisure. Amidst such a host of plants as is here to be seen, it cannot be a matter

FIG. 94.—LÆLIO-CATTLEYA INTERMEDIO-FLAVA GOLDEN GEM.

for surprise that there should be such distinctiveness as in the growth, and this alone shows how varied is the stock. As a matter of fact there are many that none but an expert would recognise as being forms of elegans. Some have growths and leaves approaching closely to the size of those of *L. purpurata*, while others are very small. The shape of them, too, varies almost as much as does the size, but that they are elegans there can be no doubt, and it is quite as certain that the finest forms in cultivation are to be found amongst them.

Having seen and admired those mentioned, we passed through several houses of Cattleyas, and observed in flower some varieties of Mossiæ and Mendeli, with many specimens of gigas, Trianae, a splendid stock of *Lawrenceana intermedia alba labiata*, including more than one white variety, Mantini nobilior, Schröderæ, Gaskelliana, Bowringiana, and others beyond number. Lælias of the purpurata type, Lælio-Cattleyas, and Lælias tenebrosa and præstans alba, some in and out of bloom, were seen, besides scores of grand plants of *Cœlogynes* in a house to themselves. Angraecums, Anguloas, Vandas, Thunias, and Dendrobiums claimed attention in passing by reason either of the beauty of their flowers or the excellence of their several growths. Dendrobium Phalaenopsis are in great form, as are Phalaenopsis, whose tough leaves appear to be in the very best of condition. They occupy a front stage in a house on the back stage of which Anthuriums flourish, and the conditions are palpably congenial to all.

In an earlier paragraph brief reference was made to the Woodlands system of planting Orchids in beds on the stages, for which purpose Cymbidiums are great favourites. That the plan suits them is proved by the splendid condition of the stock, and it is a fact that many improve after the planting. Several species and varieties are utilised for the purpose in one structure, which also contains four plants of *Lælia purpurata*, that were turned out of pots because they were somewhat sickly; now they look well, and are making good headway. Another lofty conservatory has been built up with tufa rock, and is entirely occupied with Cymbidiums, which will, when well established, make a very charming display. Amongst the several other Orchids that were subjected to this treatment were *Cypripedium insigne* and *Odontoglossum grande*, each of which was in a very satisfactory state. Needless to say the use of dwarf trailing plants as a groundwork greatly enhances the effect produced by all these plants.

Hanging from the roof of one of the Cattleya houses was one of the finest collections of *Odontoglossum citrosum* it has been my pleasure to see. It is not included amongst those Orchids which are easy to grow; but at Streatham it luxuriates, and its requirements are evidently thoroughly understood. In cooler quarters are *Odontoglossums* crispum, Pescatorei, polyxanthum, and many besides, which were, when this visit was paid, looking very bright. Spikes of variously sized and coloured flowers were numerous, and the plants carried stout foliage of a deep green hue. *Miltonia vexillaria*, too, is well grown, and some charming varieties were noticed as we passed along. The flowers were of good average size, and ranged in colour from pure white to the richest rose.

Though the flowers are so short-lived few Orchid growers would care to exclude Sobralias from their houses, for some of them are of singular beauty. The blooms are here to-day and gone to-morrow, but they are nevertheless appreciated. Some of the most conspicuous at The Woodlands were Lowi, Amesiana, Measuresiana, Hookeræ, Kinballiana, and alba, but these were not all in flower. Lycastes, too, are numerous, but the same might be said of others, for the mention of which space cannot now be found. It was a pleasant treat to see the splendid plants in such immense numbers, and visits to see the *Lælia elegans* and *Cypripedium insigne* will be looked forward to with eagerness until their flowering times come round again.—H. J. WRIGHT.

FLORA OF TIBET.—During the last five years the Kew Herbarium has been enriched by a number of collections of dried plants from various parts of Tibet, some particulars of which have appeared in the "Kew Bulletin" from time to time. (See 1893, p. 369; 1894, p. 136; and 1896, pp. 99 and 207-216; also Hemsley in the "Journal of the Linnean Society," xxx., pp. 101-140, plates 4 and 5.) Several other small collections have reached Kew since; and one, by far the largest ever received from Tibet, was presented last July, but has not as yet been completely examined on account of the pressure of other work. This collection was made by H. E. Hobson, Esq., who is stationed at Yatung, on the eastern frontier of Sikkim and Western Chumbi, between Yakla and Gnatong. Botanically it is in the humid Himalayan region, where the vegetation is comparatively luxuriant and diversified, whereas all the collections previously noticed are from the arid sterile country, which begins a very little to the north. Mr. Hobson's collection consists of about 1500 specimens, largely of herbaceous plants, amongst which there are doubtless a good many novelties.—("Kew Bulletin.")

ROYAL HORTICULTURAL SOCIETY'S ROSE SHOW, CHANGE OF DATE.

MAY I ask you to be so kind as to announce, in as prominent a manner as possible, that the Council have changed the date of the R.H.S. Rose Show, advertised on page 59 of the Arrangements for 1898, from June 28th to July 12th? This alteration is necessitated by the abnormally backward state of the Roses this year.—W. WILKS, Secretary.

ROYAL ROSES.

WE are informed that on the occasion of the recent Floral Fête at the Royal Botanic Society's Garden, Regent's Park, the Prince of Wales was graciously pleased to name one of Messrs. Wm. Paul & Son's seedling Roses "The Alexandra," and to accept blooms of it. His Royal Highness also specially admired Messrs. Paul's new variety "Empress Alexandra of Russia."

ROSES AT THE EARLY SHOWS.

IT is a matter for regret that the long-continued untoward weather has somewhat marred the prospects of the early shows. Mr. C. W. Simmons, the well-known York Secretary, informs us that Rose entries are rather short. This is unfortunate, for as a rule the queen of flowers is seen in grand form in the northern city. We see by our advertisement columns, too, that the Isle of Wight Show, which was fixed for June 16th at Carisbrooke Castle, has had to be postponed owing to the lateness of the flowers. We hope things will brighten for the later exhibitions, but so far as we have heard results are not very promising.

NOTES ON CHOICE WALL ROSES.

ROSES on walls are now coming into flower, being favoured by position, warmth, and shelter in many cases from cutting winds, whereby they can produce blooms earlier than plants in the open ground. There is a wealth of wall Roses, but the choicest are undoubtedly the Teas and Noisettes. Some of them are better adapted for growing on walls and fences than any other method of cultivation, for the reason that they make long, strong shoots, and are generally robust in habit.

The hardiest of our Tea Roses, Gloire de Dijon, is one of the earliest and the freest in flowering, producing buff-coloured blooms in abundance at the point of every young shoot when a plant is in good health. On a warm wall facing south, either of a dwelling-house or a glass structure, few Roses seem to succeed better. Even after its first flush of beauty blooms will continue to be produced, which makes it almost a continuous flowering plant during the season.

Reine Marie Henriette is another Tea very similar in growth and habit to Gloire de Dijon, but its blooms afford a decided contrast, being deep red. It is an excellent wall Rose. Cheshunt Hybrid is also similar in habit and nature of growth, which is very free. The blooms differ in colour. They are cherry carmine.

A Rose of a totally different class has attained popularity of late years. It is the vigorous Crimson Rambler, styled a hybrid Polyantha. The flowers are borne in trusses of pyramidal shape, and the colour of the blooms, as the name of the Rose implies, is crimson.

William Allen Richardson, belonging to the Noisette class, is a remarkably useful Rose, and is considered in numerous cases to be worthy always of space for culture under glass, but one or two plants should be grown outside to afford a succession, selecting a favourable position. The blooms are of a deep orange colour, and the plant is almost a continuous bloomer. Rêve d'Or and L'Idéal are also Noisettes. The former is one of the hardiest of this class; colour, buff yellow. The latter is specially sweet scented, giving it an additional claim to be ranked as a good Rose. A white climbing Rose is indispensable. In Climbing Nipbetos we have a strong grower and free bloomer.

In the course of the summer long strong shoots will be thrown out from various parts of the trees. The best of these must be reserved, given every facility to ripen, and be finally trained in to form the blooming wood for the following season. During growth and flowering plenty of moisture at the roots is essential. It is, however, in danger of being deficient when trees are growing in positions where there is a probability of the rainfall not reaching the soil in sufficient amount for the requirements of the trees. Wall Roses are frequently unfairly treated in respect of moisture, suffering in consequence, growing weakly, and flowering indifferently the following season, if not during the current year.

Roses appreciate liquid manure. The best time to give it is in moist weather, or when the soil about the roots has been first moistened. It then enriches the soil and provides food in a readily available form. The effect of an application may soon be seen in the improved appearance of the foliage, the tendency to push new growths not only from the younger parts of the trees, but from the older. The flower buds plump up and the blooms open more readily.

The varieties above mentioned are well adapted to furnish the higher spaces of walls, but they do not readily clothe the lower parts, hence it is necessary when planting to intersperse varieties which will furnish the base of the wall effectively. Of the two classes of Roses, Teas and Noisettes, these dwarfier growing varieties are only found in the Tea

class, but there is a fairly wide selection able to fulfil the conditions required. The best white variety for the latter purpose is The Bride, and the next nearest in colour to it is Rubens, creamy white. A deep yellow is found in Perle des Jardins, and a pale yellow in Marie Van Houtte. Anna Olivier and Catherine Mermet are rosy fleshed varieties; Madame Falcot and Sunset, deep apricot colour. A good red variety is Madame Lambard.

These are not weakly growing Roses, but, on the contrary, they make strong growths, which, however, do not extend to the length of those previously named. As the shoots are produced it is desirable to lay them in, but not so as to crowd the growths unduly. Allowed to ramble in all directions the shoots become stiff and unshapely, which makes it difficult to place them in position as may be desired. Weakly growths may be cut out at any time to make room for more vigorous wood. Such will produce the best blooms if trained thinly and thoroughly ripened.—E. D. S.

WEATHER IN LONDON.—On Thursday and Friday of last week the rain descended in torrents at frequent intervals, this being especially the case of the latter day. Saturday was warm and genial, the sun shining brightly the whole day, while Sunday and Monday were dull and cold. On Monday night the wind was high, and more suggestive of November than June. Tuesday was dull and cold. Wednesday a little warmer.

WEATHER IN THE NORTH.—Since the 14th the weather has been dry, and the first three days especially warm and bright. On the evening of Friday the wind again set into the east, and rather duller days and a lower evening temperature have obtained.—B. D., *S. Perthshire*.

A PLAGUE OF FLIES.—A plague of aphides, or green fly, has attacked the fruit gardens and orchards in certain districts of north and mid-Herts. Bushes hitherto bearing abundant promise of fruit are now withering, and in the Hitchin district the Rose trees are covered with the diminutive pest. It is many years since the gardens in Hertfordshire suffered from a similar visitation.

METROPOLITAN PUBLIC GARDENS ASSOCIATION.—We learn that this Association has completed the laying out of the recreation grounds at East Street, S.E., and in Charles Square, N., and these are now open to the public; while the grounds in York Street and Kipling Street, S.E., are approaching completion. The West Ham Corporation has agreed to maintain a disused churchyard at Plaistow, E., which the Association had offered to turn into a public garden. The Association hopes to be able soon to lay out the Paragon, S.E., and a neglected square in Dalston.

EAST COWES.—At the last fortnightly meeting (held on June 8th) of the East Cowes Horticultural Society, presided over by Mr. G. Groves, J.P., C.C., the first of a series of lectures was commenced by Mr. S. Heaton, Horticultural Instructor for the I.W.C.C. The subject chosen by the members was "The Cultivation of Specimen Greenhouse Plants for Amateurs and Cottagers." Previous to dealing with the various foliage and flowering greenhouse plants, the lecturer gave some valuable advice on potting, watering, syringing, feeding, training, staking, tying, packing, staging, and labelling plants. At the close a unanimous vote of thanks was accorded the lecturer, on the proposition of the Chairman, seconded by Mr. Chas. Martin, and supported by Messrs. J. Hygate and A. Saunders.

MALMAISON CARNATIONS.—Amongst first-class growers of these Carnations a very high place must be given to Mr. McLeod of Dover House Gardens, Roehampton. This grower has now a splendid collection. The finest, some five dozen or six dozen, are in 9½-inch pots. They are about 3 feet in height, and as much through, and carrying many large flowers. All are about two years and six months from thumb pots, and exhibit superb cultivation. Mr. McLeod favours dry treatment, especially in the winter, when too much air can hardly be given. Watering is done sparingly, and all parts of the house are kept dry. Associated with the ordinary pink and carmine varieties are younger plants of that rich scarlet variety, the Churchwarden. These, as also a large number of younger plants of the old varieties, in perfect health, and all will next year make very fine plants. The large ones have been in their present pots two years.—D.

HEUCHERA SANGUINEA.—This plant, which belongs to the natural order Saxifragaceae, is now blooming very prettily in borders and rockeries. The flowers, rich coral pink in colour, are borne on erect slender stems, arranged thereon in loose panicles. They are useful for cutting, forming a tasteful decoration when placed in a glass loosely with a little of their own foliage. The plant is quite hardy, and succeeds in a comparatively dry and poor position. A stock of it may be raised from seed, sowing in a box and transplanting finally when large enough. Flowers appear the second year.—E. D. S.

A WEATHER CONTRAST.—The contrast between the weather of last Saturday and Sunday was, says a paragraph in the "Daily News," extraordinary. On Saturday we were favoured with a burst of summer warmth, the sun shining brightly nearly all day, and the thermometer in London rising in the shade to a maximum of 77°. Sunday seemed to take us back with a plunge into quite another climate, the sky being continuously dull and gloomy, with a temperature at no time exceeding 56°. Saturday's reading was, in fact, 8° above the June average, while Sunday's was as many as 13° below it, the maximum of 56° being about equal to the average for the months of April and October.

THE WEATHER LAST MONTH.—The wind was in a westerly direction nineteen days. Total rainfall, 2.71 inches; this fell on twenty-one days, and is 0.35 inch above the average for the month. The greatest daily fall was 0.33 inch on the 27th; barometer (corrected and reduced), highest reading 30.352 inches on the 7th at 9 A.M., lowest 29.126 inches on the 11th at 9 A.M. Thermometers: highest in the shade, 68° on the 23rd; lowest, 30° on the 19th; mean of daily maxima, 56.19°; mean of daily minima, 39.12°. Mean temperature of the month 47.65°. Lowest on the grass, 30° on the 19th; highest in the sun, 133° on the 11th. Mean temperature of the earth at 3 feet, 49.25°. Total sunshine 151 hrs. 45 min. There were five sunless days.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham*.

WEATHER AT DOWLAIS.—Total rainfall for the past month, 4.23 inches, which fell on twenty-one days; greatest fall, 0.44, which fell on the 25th. Mean maximum temperature, 60.8°; highest reading, 82° on the 23rd; mean minimum, 37°; lowest reading, 26° on the 15th and 16th. Below freezing point on five nights, and was under 40° on eighteen nights. The surrounding hills were covered with snow in the second week, and snow also fell on the 1st of June, with the night temperature down to 32°. There were eight sunless days, the total amount of sunshine only reaching ninety-four hours, or forty-seven less than in April. The wind was in the W. and N.W. on sixteen days, and in the E. and N.E. on eight days, and has been bitterly cold throughout the month. On the 18th and 19th it was blowing quite a gale, and was piercingly cold; quite a repetition of the gale we had in March. On the afternoon of the 22nd we had a very heavy hailstorm, with stones of a very large size, doing a great amount of damage to various foliage, especially Chrysanthemums, the plants afterwards presenting a sorry spectacle.—WM. MABBOTT, *Gwernllwyn House, Dowlais*.

SUPPLYING FLOWERS TO SCHOOLS FROM THE PUBLIC PARKS.—The School Management Committee reported that they had had their attention called by their Chairman to a report as follows from the British Embassy at Berlin, giving the arrangements made in Berlin for supplying primary schools with flowers from the public parks: "In the town gardens here (Berlin), and especially in 'Humboldt-Hain,' flowers are gathered in proportionate quantities during the summer months of the year, and are placed at the disposal of the upper grade and lower grade municipal schools, at their desire, and also at the disposal of private schools for a consideration, for the purpose of furthering the study of botany. The flowers are sent to the schools in especially ordered carts twice a week; they are sent in bundles, each bundle containing fifty specimens of the same species of plant, and only one bundle falls to each botany class. The names of the plants which may be expected during the week are published every Sunday in the public Press. Flowers from the town gardens are not supplied for the decoration of schools, or making presents of them to scholars." The Committee were of opinion that similar arrangements might possibly be made in London, and with a view to achieving that object recommended that letters be addressed to the London County Council and to her Majesty's Office of Works, setting forth the arrangements which were now made in Berlin for supplying flowers from the public parks to the elementary schools, and inquiring whether somewhat similar arrangements could not be made for the benefit of public elementary and other schools in London. On the motion of Mr. Graham Wallas it was decided that letters be addressed to the London County Council and to her Majesty's Office of Works with reference to supplying flowers to schools in accordance with the terms of the report.

— THE SCENT OF TULIPS.—Your note regarding the fragrance of *T. macrospila*, appended to my remarks on late garden Tulips in the Journal of June 2nd (page 460) has been left unnoticed on account of my absence from home. *T. macrospila* is one of the comparatively few fragrant Tulips, and, as such, deserves to be more largely grown, even if it were less beautiful than it is. It would be interesting to know what Tulips are really fragrant. *T. suaveolens* should be sweet-scented, and is so, but, I think, to a less degree than *macrospila*. There is an old brown one I have here which is distinctly fragrant, but I have no name for it, although I think it is only an old garden "breeder," which must have remained unbroken for many years.—S. ARNOTT.

— WAKEFIELD PAXTON SOCIETY.—Programme of meetings for the second quarter—Session 1898. June 11th, Visit to Hebden Bridge for Hardcastle Craggs; 18th, "Hardy Flowers"—choice and interesting kinds, with some specimens, Mr. John Wood, Kirkstall; 25th, Wild Flower Exhibition, Mr. Rd. Ainley, Morley; July 2nd, "Symbiosis and Parasitism," Mr. J. W. D. McPherson, B.A., Wakefield; 9th, "The Strawberry," Mr. J. G. Brown, Wakefield; 16th, the Rose Exhibition, Mr. G. Bott, Walton; 23rd, Visit to Askern and Campsall Hall; 30th, "The Canna," Mr. Arnold S. Nicholson, M.S.A., Wakefield; August 6th, the Carnation and Picotee Exhibition, Dr. Hein, Wakefield; 13th, the Pelargonium Exhibition, Mr. J. Thomas, Wakefield; 20th, "The Lily Order," Mr. W. H. Vere, Milnthorpe; 27th, Visit to Rishworth. For full particulars, apply to Messrs. T. H. Mountain and A. S. Nicholson, the Hon. Secs.

— MESSRS. SUTTON & SONS' EXCURSION.—The annual excursion given to the employes of Messrs. Sutton & Sons of Reading, the Queen's seedsmen, took place on Monday. The destination chosen was Southampton and the Isle of Wight, travelling by way of Newbury, and then over the Didcot, Newbury, and Southampton Railway to Southampton. The weather was wet on the journey down, but fortunately it cleared on arrival at Southampton, and the rest of the day was fine, and the trip most enjoyable. Two steamers were chartered by the firm to convey the party, which numbered 670, to different parts of the Island. The first left for Ryde, Sandown, Shanklin, and Ventnor, and the second for Trinity Wharf, Cowes (for Osborne), Totland Bay, and Ryde. Her Majesty the Queen graciously arranged for the members of the party to visit Osborne, and they were shown over the grounds by Mr. Slater, agent of the Osborne estate, and Mr. Nobbs, head gardener. A fine view was obtained from the terrace at Osborne. The following members of the firm and their relatives accompanied the excursion:—Mr. and Mrs. Martin John Sutton, Mr. Arthur W. Sutton, Mr. Leonard Sutton, Mr. M. H. F. Sutton, Miss Jessie Sutton, Miss Kathleen Sutton and Master Phil Sutton, Master Arthur Pym Sutton. By the liberality of the firm every one of the employes had tickets free, each married man had a ticket for his wife, and every employe was provided with money for refreshments during the day. The return train left Southampton at eight o'clock, arriving in Reading about ten o'clock, all having spent an enjoyable day at the seaside.

— MANGOSTEENS FROM THE WEST INDIES.—Plants of this well-known and delicious tropical fruit have been widely distributed from Kew to the West Indies. The Mangosteen is a native of the Molucca Islands, and is cultivated in the Straits Settlement, Java, and in one or two localities in India and Ceylon. The fruit is regularly shipped from Singapore to the Calcutta market. The first West Indian fruits were produced at the Botanic Gardens, Trinidad, in 1875. In September, 1891, the Governor of that island forwarded some West India Mangosteens for presentation to her Majesty the Queen. The Mangosteen fruited for the first time in the Jamaica Botanic Gardens in 1886 ("Kew Bulletin," 1895, page 79). Last year a box was received at Kew from Mr. J. H. Hart, F.L.S., of Trinidad, containing nine fruits of Mangosteen, which were perhaps the first to reach this country in a condition to allow their merits to be appreciated. Each fruit was separately packed in a compartment with pine wool. Owing to the firm consistency of the outer wall of the fruit it appears to travel well. The fruits were distributed to the Secretary of State for the Colonies and others. The reports received were uniformly favourable. One fruit was sent to Mr. George Munro, one of the leading fruit merchants in Covent Garden, to obtain an opinion as to prospects of shipments of Mangosteens to this country. Mr. Munro reported:—"Yours to hand. I cut open the fruit and showed it to some of my best customers, and they think with me that, if they came in good condition, and not too many at first, a business could be worked up in them. At any rate I should like to try some, and if sent, will do all I can to get a trade for them. They appear to be a fruit that would carry well."—"Kew Bulletin."

— EVAPORATED VEGETABLES.—These form an industry carried on by Mr. F. A. Pulleine of Lobethal, South Australia, who, according to an Australian contemporary, is "making a name for desiccated vegetables and fruits; and, although several others are in the habit of evaporating fruits on a large scale and make a first-class article, he is the only one, so far as we know, who deals with vegetables during the off season for fruits. Carrots, Parsnips, and Potatoes are reduced to about one-eighth part of their original bulk and weight; Onions are brought down to one-twentieth part. Reduced thus in bulk and weight, vegetables can be transported to distant parts at a very moderate cost, and they will keep perfectly good for two or three years. When required for use the articles are soaked in five or six times their weight of water for twenty-four hours, when they are ready for cooking like fresh vegetables."

— BIRMINGHAM GARDENERS' ASSOCIATION.—At the recent monthly meeting, for a display of specimen plants and cut flowers, Mr. W. Dodd, gardener to A. Chance, Esq., Edgbaston, exhibited a seedling small specimen of *Coleus*, which attracted considerable attention from its distinct characteristics. It was of robust habit, and the large leaves suffused with two shades of green and yellow—the latter predominating. The plant was about a year old, and proved to be the only plant possessing the colour in question out of scores of others from the same packet of seed, crossed by himself. As exhibited the plant should lend itself for decorative purposes, and to "groups for effect." Messrs. John Pope and Sons contributed cut blooms of several hardy shrubs, as did Mr. C. R. Bick, gardener to Walter Chamberlain, Esq., Harborne Hall, Harborne; whilst Mr. Walter Jones, Edgbaston (the Chairman), had a tray of very good *Calceolarias*. The proceedings were rendered additionally interesting and instructive by the discussion of various matters pertaining to floriculture amongst several of the members present.

— THE SEED CASE—HOWCROFT & WATKINS *versus* LAYCOCK.—AN IMPORTANT DECISION.—A few weeks ago the Rev. G. T. Laycock, Terwick Rectory, Petersfield, was summoned in the Westminster County Court for payment of an account for seed ordered as Couve Tronchuda, but as supplied proved to be the tall Jersey or "Walking-stick" Cabbage, and therefore worse than useless for the purpose for which the plants were grown. The vendors appear to have relied on the terms published on their invoices:—"Howcroft & Watkins give no guarantee, express or implied, as to description, quality, productiveness, or any other matter of any goods they send out, and will not be in any way responsible for the crop. If the purchaser does not accept the goods on these terms they are at once to be returned." The vendors practically won their case, but the purchaser appealed against the verdict of the County Court Judge. The case was argued before Mr. Justice Day and Mr. Justice Lawrence on the 6th and 7th inst. The former, in giving judgment, was of opinion the County Court Judge was misled. When a thing commercially known as Couve Tronchuda was ordered, that must be sold, and not something else, or there would be an end of contracts, and a new law created by vendors. To that he could not agree, and as Mr. Justice Lawrence concurred the appeal was allowed, and judgment given for Mr. Laycock, with costs in both actions. An appeal was asked for, and granted on the terms that the appellant should be indemnified as to costs. It is undoubtedly an important case, and further developments are awaited.

PRIMULA TRAILLI.

HAVING had another year's experience, I can now speak with certainty as to *Primula Trailli*. I heard from my Indian botanical friend that he had met the collector of the seed sent me as that of *P. Trailli*, and had shown him the gardening papers which I had sent to India, with figures of the plants bloomed here. These, he said, were quite different from *P. Trailli*, that he had collected other *Primula* seed at the same time as *P. Trailli*, that the seed was mixed, and that *P. Trailli* had not come up. I think the best name for the *Primula* which I exhibited would be *P. Monroi* or *P. involucrata* major. It is utterly unlike the form of *P. Monroi* or *P. involucrata*, which I have grown for years. It has when grown close to the glass, and so free from any tendency to be drawn up, stems above 18 inches high with long leaves.

Probably several of the Indian *Primroses* have different forms. Some years ago I exhibited before the Floral Committee a giant form of *P. capitata*, which I suggested should be named *P. capitata* major. This received a first-class certificate on 9th October, 1886; and some time afterwards a nurseryman exhibited a giant form of this *Primrose*, which I suppose the Committee considered different from mine, as this also secured a certificate or award. The Committee only followed the usual precedents in rewarding a fine distinct new form of *Primula* in the case of *P. Trailli*, but I think the name should be changed, and the fact recognised that *P. Trailli* has still to be introduced.—GEORGE F. WILSON.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE fifty-ninth anniversary festival dinner of this well-known charity took place at the Whitehall Rooms, Hotel Metropole, on the evening of Wednesday, June 8th. In every other respect a great success, it was marred by one disappointment—his Grace the Duke of Portland, who had been announced to take the chair, being kept away through illness. The genial presence and typical English face of Sir Oswald Mosley, Bart., of Rolleston Hall, Staffs., in the presidential chair went far, however, to compensate for the absence of his Grace. About 140 gentlemen sat down to dinner, and these constituted a representative body of all persons interested in horticulture. The Very Reverend Reynolds Hole, Dean of Rochester, was a chief and central figure, whilst other well-known faces were those of Messrs. N. N. Sherwood, A. W. Sutton, John H. Laing, H. B. May, Geo. Munro, P. Kay, H. J. Veitch, Jas. H. Veitch, P. Crowley, H. Cutbush, A. F. Barron, W. Goldring, J. Assbee, Geo. Dickson, A. W. Weeks, T. W. Sanders, Geo. Wythes, G. Reynolds, Jas. Hudson, J. F. McLeod, and J. Douglas.

receive at such times from clubs and other benefit societies. He coupled with the toast the name of Mr. H. J. Veitch, their esteemed Treasurer.

Mr. H. J. VEITCH replied at some length, and it was easy to see, by the vigour and earnestness of his manner as he was pressing the claims of the Institution upon his hearers, that his whole heart was in the matter. It had been his privilege, he said, to return thanks for the Society for a number of years, and on each occasion he had been able to report continued progress. In this instance he was glad to be able to do the same. They had now more pensioners on the books than ever before, for the number last January was 168, ninety-three of whom were men and seventy-five women. Eleanor Brown, their oldest pensioner, had lately died, and he cited her case as a good example of what the Institution does for its subscribers. Eleanor Brown's husband joined in 1850, subscribed a guinea a year for sixteen years, and was put upon the fund in 1866. He continued to draw his pension until his death, in 1875, during which time he had received a sum of £144. His wife was elected to the pension in his place, and had received £314, thus making a total sum of £458 which this worthy couple had received. They had a greater number of

FIG. 95.—GROWING "HOT AND COLD" FOR MARKET. (See page 494.)

Dinner was laid for seven o'clock, and although it was served fairly punctually, a lengthy toast list kept things lively until a late hour.

The loyal toasts of "The Queen," who has been patroness of the Society since 1851; "The Prince of Wales," who is its esteemed patron; "The Princess of Wales, and the rest of the Royal Family," were proposed by the Chairman, and, as usual, heartily received.

Sir OSWALD then proceeded with the toast of the evening—"Continued Success to the Gardeners' Royal Benevolent Institution." First of all he requested the Secretary (Mr. G. J. Ingram) to read the letter sent by the Duke of Portland. This, besides expressing the regret his Grace felt at being unable to be present, spoke of a willingness to take the chair on some future occasion. This, Sir Oswald thought, was matter for congratulation, seeing that one of the finest noblemen in the country was interested in the Institution. Speaking for himself, he said that in his young days he knew very little, and cared less, about horticulture; and, indeed, the first introduction he had to the art was to what he then thought a very nasty tree, the "Birch;" but as he had grown older he had grown wiser. He had tried horses, but had found them expensive, therefore he had practically given them up, and had taken to gardening, thus following one of his ancestors—his grandfather—who had been a great gardener and a great botanist. It behoved everyone, he said, who had the interests of horticulture at heart to try and persuade gardeners to help themselves. To this end employers ought to pay their employees their full wage during sickness, irrespective of any sums they might

applicants for the pension now than formerly, for whereas ten years ago there were twenty-seven, this year fifty-four applied for relief—just double.

He wished that more gardeners would subscribe. One reason for their not doing so was, perhaps, that the Institution was not so well known as it ought to be, but he thought a more likely reason was that the wages of the gardener had not increased in proportion to the rise of wage given in other trades. Mr. Veitch then read three advertisements, of the class for the cow, pig, and poultry-minder and gardener that is so often seen, the wages offered being 15s., 18s., and 21s. weekly respectively in the three advertisements, or lower than those of a town labourer. He did not contend that these were the average situations offered, but cited them to show what was often asked for at an impossible wage.

Speaking of the Victorian Era Fund, he said that they had asked for £5000, and had obtained £4000, which was gratifying, when the number of appeals to charity made during Jubilee year was considered. Of the remaining £1000, necessary to complete the scheme, £200 was already promised. Mr. Veitch then made a strong appeal to the benevolent instincts of his hearers, pointing out that over £3000 was needed annually to discharge the liabilities to pensioners already on the books, to say nothing of working expenses, or any increase in the number of pensions. He commended, both to his audience and himself, the example of a great gardener (Mr. J. W. Thomson), who at his death left legacies to the horticultural charities.

The auxiliary societies at Bath, Wolverhampton, Bristol, and Worcester were doing great things, and they hoped to see one established soon at Reading, where Mr. Arthur W. Sutton was pushing the cause strenuously. In conclusion, he reminded his audience that the Institution was carried on for those who, through unavoidable circumstances, were led in their old days to seek its benefits, and who in their earlier years had done so much to add to the pleasure and gratification of others.

Dean HOLE is so well known for fluency of speech that expectation ran high when he rose to propose the toast of "Gardening." Nor were the expectations disappointed, for the Dean charmed everyone by his boundless store of anecdote and apt simile, not less than by his eloquent delivery. He opened by remarking that the poet Horace had said that "he was a bold man who first went to sea in a boat," that "he must have had a heart of brass and a constitution of oak." Someone else, too, had said that "he was a bold man who first ate an oyster." In his estimation, however, the boldest man was he who asked the Dean of Rochester to speak upon gardening, for how could he know when the very reverend gentleman would stop. Gardeners had a great deal to suffer. They had to talk to people who profess to care about gardens, but who do not really care twopence, and who will talk about the Eton and Harrow match, or anything else rather than gardening. Personally he had had a love for flowers from very early infancy, for it had been stated, with what truth he knew not, that one of his nurses had given warning because he would grab the flowers out of her Sunday bonnet. It was absolutely true, however, that the love for flowers was innate in every human being, that it was a memory of Paradise lost, and a hope of Paradise regained.

He had vivid recollections of his first *Salvia*, for which he gave sixpence. A boy who was bigger than he said the plant was sick, and gave it some beer, and, continued the Dean, "I defied him to mortal combat, and licked him in three rounds."

As he grew older there came a period of apathy and indifference, when the "Mary" he loved best was not *Marigold* nor *Polyanthus*, when his "Annie" was not *Anagallis*, when his "Carrie" was not *Caryota*, when the "Miss" whom best he liked was not *Mesembryanthemum*, and when, even although he loved "*Marguerite*," he gazed upon her with quite a lackadaisical expression. Since then his love for flowers had happily returned to him, never more, please God, to leave him. He had seen the scarlet and yellow fever which had swept over the country, the Tom Thumb *Pelargonium* and the yellow *Calceolaria*, but that had to a large extent passed, although some gardens were still afflicted. Since we had recovered from this terrible ballucination, gardening in all its branches had made enormous progress. Fruits, flowers, and vegetables all showed the same trend. Yet although we lived in a country in which more beautiful flowers could be had than in any other, he was not satisfied. We wanted more gardens, and more beautiful gardens. What advantages were possessed by the various farmers scattered through the land! For himself he loved cows and pigs, not only in the shape of beef and pork, but for the grand manures they produced—a cartload of manure was to him the sweetest of perfumes.

The Dean went on to say that we wanted more beauty of arrangement in our gardens. There were far too many straight lines in gravel walks, and too many instances where the whole of the gardens could be seen from the windows of the dwelling-house. We wanted gardens in which children could play hide-and-seek, and lovers could dream, and he made a strong appeal for the simple, natural, old English garden.

Speaking specially of the Rose, the very reverend gentleman said that he had long loved the Rose, and believed that there was a splendid future before rosarians. He looked to the new class, the Hybrid Tea, introduced by Mr. Bennett, Mr. Dickson, and the Messrs. Paul, to eclipse all other sections of the Queen of Flowers.

For more than half a century he had enjoyed the fellowship and brotherly sympathy of gardeners. He had been an enthusiastic foxhunter, had played bowls and cricket, had dabbled in archery, and had mixed with the keenest votaries of these games, but nowhere had he experienced so much sympathy and fellow feeling as amongst the gardeners. It was all the same, both from coronets and billycocks, in ducal balls and in humble cottages. And when he crossed the Atlantic, there was scarcely an hotel in the United States where he did not find awaiting him a box of Roses or Carnations, tributes of love and fraternity. A gardener was a friend at all times, and a brother born for adversity. The Dean concluded his eloquent address by saying that the work of the Gardeners' Royal Benevolent Institution was fully deserving of the blessing that came upon the prophet of old—"The blessing of him that was ready to perish came upon me, and I caused the widow's heart to sing for joy." Coupled with the toast was the name of Mr. A. W. SUTTON.

That gentleman replied in a few words, in which he drew attention to the fact that the state of their gardens would depend upon their gardeners, hence it was incumbent upon them to do all they could for the gardener. He spoke appreciatively of that standard work, "*The History of Gardening in England*," written by the Hon. Alicia Amherst, now Mrs. Evelyn Cecil. The clergy had done much to advance the cause, and in addition to the Dean of Rochester, gentlemen like the Rev. W. Wilks, Rev. G. Engleheart, and Rev. H. D'Ombraim had achieved much. The members of the Royal Family were great gardeners, and he instanced her Majesty's love for it as exhibited by the way in which, according to her express instructions, the nine little gardens at Osborne, formerly belonging to the young Princes and Princesses, were still cared for, and the produce duly taken to Her Majesty's table. With regard to the proposed branch society at Reading, he thought that Mr. C. E. Keyser of Aldermaston would become its president.

Mr. GEO. MUNRO then gave "Our Country Friends;" the first time, he said, that it had ever been proposed there as a toast. The work these auxiliaries were doing could not be valued too highly, for they were interesting people who have hitherto been inclined to regard the Institution as a London one simply. He could not refrain from mentioning in this connection Mr. White of Worcester and Mr. George Dickson of Chester, both of whom had worked hard and consistently for the Society. It was painfully instructive to learn, however, how comparatively little the Institution was known, for while there was one county with 183 subscribers, there were eleven that had less than ten each, and three counties with only one subscriber in each. This only showed what a lot of fallow ground there was to break up, what a lot remained for them to do. Mr. GEO. DICKSON, whose name was associated with the toast, responded very briefly.

The amount of the evening's subscriptions was then announced by the Secretary, and was found to reach a grand total of £2300, inclusive of subscriptions and donations to the Institution and the Victorian Era Fund. The following are the chief subscribers to this very gratifying total:—His Grace the Duke of Portland, 50 guineas; Sir Oswald Mosley, donation 50 guineas and annual subscription £10; Messrs. Rothschild, 100 guineas; Mr. Coleman, 50 guineas; Messrs. Hurst and Son, £20; Mr. N. N. Sherwood, £50; Mr. W. Sherwood, 5 guineas; Mr. E. Sherwood, 5 guineas; Miss Sherwood, 5 guineas; Messrs. Dickson and Robinson, £35; Mr. A. W. Sutton, £50; Mr. M. H. F. Sutton, £25; Messrs. Jas. Veitch & Son, Ltd, £20; Mr. H. J. Veitch, £50; Mr. Leonard Sutton, £50; Mr. G. Munro (list), £131; Baron Schröder, £20; Mr. A. Wilson, £20; Lord Wantage, 10 guineas; Mr. T. W. Bond, 14 guineas; Mr. Geo. Norman, £15 5s.; Mr. W. Thomson, 20 guineas; Mr. G. Maycock, £10; Mr. N. C. Cohen, 5 guineas; Mr. P. Blair, £5; Mr. W. Crump, £20; Dean Hole, £5; Mr. W. Jinks, £18 10s.; Mr. W. Y. Baker, 13 guineas; Mr. Chas. Turner, 5 guineas; Mr. B. F. Smith, 2 guineas; Mr. P. Crowley, 6 guineas; Messrs. Wrench & Son, 5 guineas; Mr. G. H. Richards, 10 guineas; Messrs. Fisher, Son and Sibray, 10 guineas; Mr. W. J. Corrie, 5 guineas; Mr. J. F. McLeod, 2 guineas; and Worcester Auxiliary, £70. It was announced that the list opened by Mr. Geo. Dickson was not yet completed, but when closed it would total from £50 to £100.

At the close Mr. N. N. SHERWOOD invited all to drink to the health of their Chairman, Sir Oswald Mosley, who was a great patron of horticulture. His gardens at Rolleston were opened frequently to the public, and in this and other ways he was the *beau ideal* of a real old English country gentleman. In replying, Sir Oswald expressed his pleasure at being amongst them, and assured them that if at any time any of them should be in the neighbourhood of Rolleston, it would give him great pleasure to show them round himself. In conclusion he spoke of the work of their Secretary, Mr. Ingram, in highly appreciative terms.

The speeches and toasts were agreeably interspersed with, and varied by vocal and instrumental music, Mr. Herbert Schartau, as on other occasions, proving himself a successful entertainer, as well as organiser of entertainers. The songs by Mesdames J. Lucie Johnstone, and Edith Serpell, and Messrs. Schartau and Chas. Chilley, were much applauded, whilst the really humorous sketch by Mr. Walter Churcher did not lack its setting of responsive laughter. The tables were handsomely decorated with flowers and plants supplied by Messrs. Sander & Co of St. Albans.

A HOLIDAY TOUR.

DURING a recent visit to Kirkbean parish in Kirkcudbrightshire, on my way to London, I was shown near Southwick (the residence of Sir Mark J. Stewart, M.P.) a magnificent Silver Fir with a trunk 18 feet in circumference, and above 80 feet high, rivalling, if not eclipsing, the famous variety at Traquair, in Peeblesshire, which I have previously described in the *Journal of Horticulture*. On the same day I visited the beautiful gardens at Southwick and Cavens; the former of which is celebrated for Anemones and Begonias, the latter for the culture of Oriental Lilies. The head gardener to A. Oswald, Esq., at Cavens told me he had a specimen of *Lilium giganteum* last year which grew upwards like a tree to a height of 13 feet, and produced twenty-one perfectly developed flowers. It is seldom that this great Himalayan Lily attains in any region to such imposing dimensions.

I was accompanied to the gardens of Cavens House by your accomplished contributor, Mr. S. Arnott, whose collection of alpine and herbaceous flowers at Carsethorn on the Solway I found, as I had anticipated, wonderfully attractive. For brightness and fragrance the garden of Mr. Arnott could not easily be surpassed. His late flowering Tulips, Narcissi, and Auriculas were especially impressive. In his congenial company I spent many hours, on a day of brilliant sunlight and perfect peace, examining and admiring his flowers, which have come to him from all parts of the world.

During the same week I re-visited several of the great English horticulturists, including Mr. Wm. Paul of Waltham Cross, who showed me several new and highly interesting Roses of his own, raised by himself; Mr. T. F. Rivers of Sawbridgeworth, Mr. F. Sander of St. Albans, Messrs. Veitch and Sons and Mr. Wm. Bull of Chelsea, Mr. J. S. Baker of Kew, who has a veritable genius for plant classification; and Mr. Harry Turner, who showed me the grand collection of Carnations, Roses, and Pelargoniums at the Royal Nurseries, Slough.—DAVID R. WILLIAMSON.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—JUNE 14TH.

THE Drill Hall on Tuesday presented a very gay appearance, and was well filled with exhibits of a diversified character. Carnations from Dover House were grand, as were Cannas, Pæonies, and Rhododendrons from various growers. Orchids were of great interest, but not very numerous.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with Rev. W. Wilks, and Messrs. T. F. Rivers, J. Cheal, J. Willard, A. F. Barron, G. Norman, F. Q. Lane, J. Smith, H. Balderson, G. Wythes, G. Woodward, T. G. Miles, A. Dean, and J. Wright.

Mr. J. Prowse, Hall Barn Gardens, Beaconsfield, Bucks, sent seed of a second early Cabbage to Chiswick last year. It was sown in August, and plants were placed before the Committee. The hearts were medium-sized, conical, and tender-looking, with few outside leaves. The variety is named *Beaconsfield*, and was granted an award of merit.

Mr. S. Mortimer, Rowledge, Farnham, sent a box of splendid fruits of Cucumber "*Sensation*," which was granted a certificate in 1896, and this was confirmed. Mr. Mortimer also sent a box of fruits of his new Cucumber, *The Keeper*. It resulted from a cross between Improved Telegraph and Duke of Edinburgh. Fruits of good length, uniform, very dark, with prominent spines, and covered with a meal-like bloom. Some of the fruits had been kept since the Temple Show, and seemed practically as firm as ever. It should prove a valuable market Cucumber if a free bearer. An award of merit was unanimously granted.

Mr. E. Beckett, Elstree House, sent Spinach with leaves of extraordinary size, measuring 16 x 15 inches. A cultural commendation was granted to Mr. Beckett, and the variety was recommended to be tried at Chiswick. Name, "*The Carter*."

Mr. Empson, gardener to Mrs. Wingfield, Ampthill, sent fruits of a new medium sized neatly netted Melon, *Empson's Seedling*, obtained from Anthony's Favourite and Eastnor Castle. It is a white-fleshed variety, extremely tender, juicy, sweet, and refreshing. An award of merit was granted without a dissentient.

Mr. James Hudson sent from Gunnersbury House fine highly coloured fruits of Lord Napier Nectarine, for which a cultural commendation was promptly awarded. He also sent a box of Guigne Annonay Cherry, the fruits gathered from a tree against a wall in the open air. It was said to be the best in quality of all early Cherries, being ten days in advance of Early Rivers, though not so large and dark. As the fruits were marked "not to be tasted" the proposal of an award of merit for the variety could not be considered.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. Fraser, H. B. May, G. Nicholson, J. H. Fitt, G. Stevens, W. Howe, J. Hudson, J. F. McLeod, J. Fraser (Kew), W. Bain, G. Gordon, J. D. Pawle, E. Mawley, C. E. Shea, C. E. Pearson, E. T. Cook, E. Beckett, C. Blick, G. Paul, H. J. Jones, C. T. Druery, J. W. Barr, H. S. Leonard, C. E. Cant, and T. W. Sanders.

Hardy flowers in large showy bunches came from Messrs. Collins Bros., Waterloo Road. They included Geums, Gaillardias, Irises, and a charming single Pyrethrum called *Monarch*. Irises formed the backbone of the group sent by Messrs. J. Veitch & Sons, Chelsea. They were mainly forms of *Iris germanica*, and included *Agamemnon*, *Nationale*, *Darius*, Mrs. H. Darwin, *Pallida*, *Dalmatica*, *Garrick*, and others. Double Pyrethrums were also very fine, as were *Eremuri* and *Aquilegias*. Messrs. Veitch staged also *Hydrangeas* and *Hibiscus*, with *Gloxinias Philadelphus*, *Mont Blanc*, and others.

The group of Cannas sent by Messrs. H. Cannell & Sons, Swanley, made a very bright display, as the well grown plants were carrying finely formed flowers of very rich colour. Amongst the best were *Queen Charlotte*, *Duchess of York*, *Germania*, *Aurore*, *Milne Redhead*, *aurea*, *Incendie*, *Paul Bruant*, *Beauté Poitevine*, and *Comte de Bouchand*. The Swanley firm also sent a handsome exhibit of double *Begonias*, in which *Lady Blythwood*, *Myra*, Mr. Stirling Stewart, *Souvenir de P. Notting*, Mrs. Dunning, and *Lady Musgrave* were very fine. Several bunches of *Aquilegias* in variety completed this firm's stand. Mr. H. B. May, Upper Edmonton, was represented by a beautiful group of Ferns. The plants were splendidly grown, and comprised sixty varieties, all raised by Mr. May. The same firm also staged a showy yellow *Tropæolum* named *Sunlight*, and *Zonal Pelargonium Milfield Rival*.

Messrs. Sander & Co., St. Albans, made up an attractive exhibit of *Acalypha Sanderi*, *A. Godseffiana*, *Mikania Sanderi*, *Globba calophylla*, *Caladiums* Mrs. F. L. Ames, Lord Annesley, *Lady Warwick*, and Mrs. Miller Mundy, and *Begonia* Mrs. F. Sander. Mr. F. Perkins, Leamington Spa, exhibited a group of his new *Carnation Primrose Queen*. The variety appears to be very useful for cutting purposes. It is slightly fragrant. Messrs. Barr & Sons, King Street, Covent Garden, staged a very large and comprehensive collection of Irises. The most notable were *i. aphylla Gazelle*, *i. variegata Malvina*, *i. v. Regina*, *i. v. Abon Hasson*, *i. neglecta Willie Barr*, *i. Humboldt*, *i. lusitanica*, *i. dalmatica*, *Princess Beatrice*, and *i. pallida*. The same firm also staged an attractive group of hardy flowers, comprising bright Pyrethrums, Geums, *Ranunculus acris flore-pleno*, *Muscari plumosa monstrosum*, *Delphiniums* in variety, single Pæonies, and a choice collection of *Ixias*.

Messrs. F. Miller & Co., 267, Fulham Road, staged a very fragrant exhibit of Miller's Civic Mignonette, spring sown. The plants were dwarf, and the spikes large; the group was flanked with single *Petunias* of the well known market type. Messrs. J. Cheal & Sons, Crawley, staged an exhibit of hardy flowering trees and shrubs, also groups of ornamental foliage. The chief objects were *Weigela amabilis alba*, and *W. græwe-*

genii, *Genista Andreanus*, *Eurybia Gunni*, *Spiræa Van Houttei*, *Cheal's New Golden Laburnum*, and *Fraxinus argentea variegatus*.

The centre of the hall was filled with a very large group of Carnations of the *Malmaison* type by J. P. Morgan, Esq., Dover House, Roehampton (gardener, Mr. J. F. McLeod). The arrangement was excellent, the huge plants being relieved with tall *Kentias*, while a groundwork of *Maidenhair Ferns*, *Spiræa*, *Lycopodiums*, and *Caladiums* effectually hid the pots. Messrs. R. Wallace & Co., Colchester, had a very gay group of hardy plants on view. The Irises were very prettily arranged in baskets. *I. Sanspareil*, Miss Maggie, Chelles, Mrs. Darwin, *aphylla*, and Mrs. Newell were most notable in the *germanica* division. The Spanish types were well represented. *Anthericum liliastrium major*, a pure white form; *Lilium rubellum*, an attractive species; various forms of *Liliums*, all contributed to make an attractive exhibit.

Messrs. Kelway, Langport, exhibited their Pæonies, Pyrethrums, and *Delphiniums* in all their gorgeous beauty. The best Pæonies were *Cavalleria rusticana*, *Bioni*, *Maud Wild*, *Limosel*, and *Duchess of Teck*. Pyrethrums were very bright. The double forms of *Melton*, *Aphrodite*, *Pericles*, *Ovid*, *Alfred Henderson*, and *Carl Vogt*. In the single forms, the bright crimson form *Jas. Kelway* was well represented. *Delphiniums* *Aspiration*, *Princess May*, *True Blue*, *Monument*, *Albert Edward*, and *Amyas Leigh* were remarkably fine.

Messrs. Wm. Paul & Son, Waltham Cross, had an extensive display of Rhododendrons, grown at their Loughton Nurseries on loam. The colours were very bright and fresh, and the foliage all that could be desired. The same firm also staged baskets of the double Scotch Roses in variety, also some of the single forms. The miniature *Provence Spong*, a bright pink, was very showy. Hybrid Sweet Briars, Austrian Briars, and the single forms of *Rosa rugosa alba* and *rosea* completed the display. Messrs. Paul & Son, Cheshunt, staged one of their well-known collections of dwarf Cannas, grown in 5 and 6-inch pots. The best varieties were *Kate Vaughan*, *Flamingo*, *L. E. Bailey*, *Lady Fandel Phillips*, *Professor Baker*, *Sir Trevor Lawrence*, *Wm. Tofts*, and *Mr. Jas. Bailey*. Hardy herbaceous plants were also in evidence. *Pyrethrum Hamlet*, *Geum minatum*, *Aquilegia hybrids*, *Campanulas*, and *Thalictrum aquilegifolium rubrum*, amongst others, were well shown. Special mention is deserved by the huge spikes of double white *Rocket*, *Hesperis matronalis alba plena*, rivalling in proportions and purity the ordinary white Stocks. It is a subject that should be more frequently met with in herbaceous borders.

Mr. J. Russell, Richmond Nursery, Richmond, contributed to the rich display of hardy flowers with good bunches of Irises, *Campanulas*, *Pyrethrums*, *Oriental Poppies*, *Delphiniums*, *Achillea mongolica*, *Lilium umbellatum*, and *Heuchera sanguinea*, the display making a very bright exhibit. A magnificent basket of Carnations came from the Marquis of Salisbury, Hatfield (gardener, Mr. Norman). The varieties were *Miss Audrey Campbell* and *King Arthur*. The yellow plants were a mass of bloom, while the specimens of *King Arthur* fully maintained the reputation of this variety. Mr. Martin Smith, Hayes (gardener, Mr. C. Blick), exhibited a few of his new Carnations, *Lady Hermoine*, a border form, salmon pink; *King Oscar*, a red silvery *Malmaison*; and *Emma*, also a rose pink *Malmaison*.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, de B. Crawshay, R. B. White, H. M. Pollett, H. Little, A. H. Smee, H. J. Chapman, W. H. Young, E. Hill, T. W. Bond, C. Winn, W. Cobb, E. Handley, S. Courtald, T. B. Haywood, J. T. Gabriel, J. G. Fowler, W. H. White, and J. Douglas.

Messrs. J. Veitch & Sons, Ltd., occupied their customary position with an effective group of Orchids. There were not a great number of plants, but those shown were good, and comprised *Lælio-Cattleya Hippolyta*, *Tricopilia suavis alba*, *Lælio-Cattleya Canhamiana*, *Cattleya Cænone*, *C. Mossiæ*, *Reineckiana*, *Epiphronitis Veitchi*, *Disa langleyensis*, and *Disa Veitchi*. In addition to those enumerated Messrs. Veitch sent *Cattleya Mendeli virginalis*, *Lælio-Cattleya Canhamiana superba*, *L.-C. Endora splenders*, *L.-C. Endora alba*, *Epi-Cattleya radiata Bowringiana*, *Lælio-Cattleya Hippolyta aurantiaca*, and *Cattleya Gertrude*. Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, sent *Dendrobium Bensoniæ*, *Odontoglossum crispum*, *O. elegantius*, *Baroness Schröder*, *Phalænopsis Aphrodite*, *Disa kewense*, *Cœlogyne Schilleriana*, *Geodorum Augusta*, and *Bulbophyllum Lobbi*, Burford variety. A group of varieties of *Odontoglossum crispum* came from Messrs. J. McBean & Sons, Cookbridge, Sussex. Mr. H. J. Chapman, gardener to R. I. Measures, Esq., Camberwell, staged *Lælia purpurata Ernesti*. Mr. J. Hudson, Gunnersbury House, sent a magnificent specimen of *Lælia purpurata* carrying ten spikes of good flowers.

Mr. H. Whiffen, gardener to J. Bradshaw, Esq., The Grange, Southgate, staged a few Orchids, comprising *Odontoglossums*, *Lælia tenebrosa*, *Cattleya Mossiæ Reineckiana*, and *C. M. Admiral Bradshaw*. Mr. W. H. Young, Orchid grower to Sir F. Wigan, Bart., Clare Lawn, East Sheen, was represented by *Cattleya Mossiæ*, *C. M. maxima*, *Lælio-Cattleyas superba elegans*, *Canhamiana*, *Iolanthe* and *Lady Wigan*, *Cymbidium tigrinum*, *Lælia tenebrosa*, and *Scuticaria Hadweni*. Two forms of *Lælia purpurata*, one of which had the varietal name of Mrs. de Barri Crawshay, and *Cattleya Mendeli Sprite*, were shown by Mr. de Barri Crawshay, Rosefield, Sevenoaks, and Mr. W. J. Empson, gardener to Mrs. Wingfield, Ampthill, sent *Cattleya Mossiæ Wingfield's* variety.

A charming group of Orchids came from Messrs. Stanley Mobbs and Ashton, Southgate, in which the flowers were well diversified, of good form, and bright in colour. There were *Lælia purpurata* in variety, *Cattleya Mossiæ*, *Cypripedium Sir Thos. Lipton*, *C. Evenor Southgate* variety, *C. Gertrude Hollington*, *Dendrobium Victoria Regina*, and others.

Messrs. F. Sander & Co., St. Albans, exhibited *Lælio-Cattleya* Lily Measures, L.-C. Duke of York, Thunias, and Sobralias Mons. L. Linden sent from Brussels *Odontoglossum crispum* Le Czar, O. c. Morning Star, and O. c. Dallemagnæ. A lovely crispum named Prince of Wales came from Messrs. H. Low & Co., Bush Hill Park; while G. H. Bird, Esq., West Wickham, sent *Odontoglossum crispum* Bonnyanum.

H. Druce, Esq., Circus Road, N.W., sent under a glass case four *Cypripediums* named *Walkerianum*, from a cross between *concolor* and *bellatulum*; Mrs. H. Druce, from a cross between *niveum* and *bellatulum* and *bellatulum* *Drucianum*. In one form of *Walkerianum* the *bellatulum* parentage predominated, while in the other *concolor* was in the ascendant.

MEDALS.—*Floral Committee.*—Silver-gilt and Flora medals to Messrs. J. F. McLeod and H. Cannell & Sons; silver Flora medals to Messrs. Kelway & Son, and H. B. May. Silver-gilt Banksian medal to Messrs. Barr & Son, and silver Banksian medals to Messrs. W. Paul & Son, R. Wallace & Co., and G. Norman. *Orchid Committee.*—Silver Flora medals to Messrs. J. Veitch & Son, and Stanley Mobbs & Ashton; and silver Banksian medals to Messrs. J. Hudson and H. Low & Co.

CERTIFICATES AND AWARDS OF MERIT.

Begonia Commodore Dewey (H. Cannell & Sons).—A grand double scarlet variety. The flowers are of splendid shape (award of merit).

Begonia Mrs. F. Sander (F. Sander & Co.).—A fine *Begonia*. There are three distinct colours in the leaves, these being brown immediately round the stalk, silvery rose beyond that, then bright green with a brown edging (award of merit).

Caladium Lord Annesley (F. Sander & Co.).—This has resulted from a cross between *C. albanense* and a garden hybrid, and of a distinct type. The leaves are very long, and come to a sharp point. The central colour is dull crimson, and there is a band of dark green round the edge (award of merit).

Calochortus Purdyi (R. Wallace & Co.).—A beautiful *Calochortus*, of which the cream colour is almost wholly obscured by the white hairs. At the base of the flower are numerous black spots (first-class certificate).

Canna Mosaic (Paul & Son).—A good variety with yellow and scarlet flowers of fine shape (award of merit).

Canna Mrs. W. Marshall (Paul & Son).—A handsome yellow flower with numerous scarlet spots on the flower (award of merit).

Cattleya Mossiæ Madonna (Stanley Mobbs & Ashton).—The colour of this is almost pure white in the sepals, petals, and front lobe and edges of the lip. The central portion of the lip is purplish rose, and the throat yellow and crimson (award of merit).

Epi-Cattleya radiato-Bowringiana (J. Veitch & Sons).—The specific name of this bigeneric hybrid tells its colour. The flower partakes of both parents. The colour is dull bluish-purple, the stripes on the lip being brown (award of merit).

Gloxinia Galatea (J. Veitch & Sons).—This is a chastely beautiful variety, of which the colour is white, each lobe being surrounded by a band of pale blue. The throat is yellowish-green (award of merit).

Gymnogramma Alstoniæ superba (H. B. May).—This is a fine form, the gold of the fronds being very effective and conspicuous (award of merit).

Lælia purpurata Ernesti (H. J. Chapman).—The sepals and petals of this variety are pure white in colour and of good form. The lip is very pale blush in front, deepening to rose towards the throat, which is yellow with rose veins (award of merit).

Lælio-Cattleya Canhamiana superba (J. Veitch & Sons).—Superb indeed is this variety. The substantial petals and sepals are rich rose, and the grandly formed fimbriated lip bright crimson, paling slightly towards the front lobes (award of merit).

Lælio-Cattleya Duke of York (F. Sander & Co.).—This bigeneric hybrid resulted from a cross between a dark form of *Lælia elegans* and *Cattleya Bowringiana*. The colour is a deep claret purple, rather dull over the whole flower save the lip, which is bright (first-class certificate).

Lælio-Cattleya Eudora splendens (J. Veitch & Sons).—One of the handsomest Orchids in the show. The colour of the sepals and petals is soft rose, while the large open lip is deep velvety maroon. The throat is pale yellow in the front, with rose veins deeper (first-class certificate).

Lælio-Cattleya Hippolyta aurantiaca (J. Veitch & Sons).—This is a lovely variety, in which the colour is bright orange. The lip is of the same colour as the other portion of the flower, but is striped with crimson (award of merit).

Mikania Sanderi (F. Sander & Co.).—This is a conspicuous plant, with sharply pointed, heart-shaped leaves. The colour is green and very dark blackish brown, the whole surface being velvety (first-class certificate).

Odontoglossum crispum Prince of Wales (H. Low & Co.).—A grand crispum in form, size of flower, and of spike. The colour is pure white, except an occasional flush of rose. The beautiful lip is white on the front lobe, with brown blotches in the centre (first-class certificate and silver Flora medal).

Odontoglossum elegantius Baroness Schröder (W. H. White).—This is a lovely yellow flower, with abundant bright brown spots and blotches. The front lobe of the lip is white (award of merit).

Pæony Ella C. Kelway (Kelway & Son).—A superb variety. The large double flowers vary in colour from very pale blush to rich lively rose (award of merit).

Philadelphus coronarius Mont Blanc (J. Veitch & Sons).—A beautiful variety with pure white flowers profusely borne above the light green leafage. The height of the plant does not exceed 18 inches (award of merit).

Pyrethrum Lady Kildare (Kelway & Son).—A fine double flower, of a peculiar pale shade of rose, the centre being orange (award of merit).

Pyrethrum Monarch (Collins Bros.).—A fine single variety with rose coloured flowers of good size (award of merit).

Scuticaria Hadweni (W. H. Young).—The yellowish green ground of the sepals and petals of this Orchid is almost obliterated by the large patches and bars of brown. The hairy semi-open lip is white with splashes of rose (award of merit).

RANUNCULUS CORTUSÆFOLIUS.

THIS plant, "W. G. R.," which has been designated as "unquestionably the handsomest of all the Buttercups known to botanists," is a native of Madeira and the Canary Islands, being confined, it is said, to one locality in Madeira—viz., Ribeira Frio. It has been known for a considerable time, and has been described by various authorities under the

FIG. 96.—RANUNCULUS CORTUSÆFOLIUS.

names *R. Teneriffæ*, *R. grandifolius*, and *R. heucheraefolius*; but that given at the head of this note is the now accepted title. It is generally considered to be hardy, though frame protection is advised during the winter. The leaves are heart-shaped, 6 inches or more in diameter, slightly lobed, with a toothed margin. The flowers are large, fully 2 inches in diameter, of a bright golden yellow colour, are very numerous, and are borne in a panicle 2½ feet high.

Referring to its culture, a well-known gardener writes:—"To grow this *Ranunculus* successfully it must be kept in a cold airy pit or frame. When it starts in spring it should be potted firmly in a compost of half good stiff loam, a fourth of leaf soil and sand, the remainder horse droppings from an old Mushroom bed. When the pots are full of roots, weak liquid manure should be given, to encourage it to throw up strong flower spikes, and assist it to make strong roots for another season. To increase the stock it should be divided as soon as it commences growing, as I have not yet succeeded in raising seedlings. It continues in bloom from six to eight weeks."

ROYAL NATIONAL TULIP SOCIETY.

[MIDDLETON.]

THE Northern Show of the Tulip Society was held in the Free Library, Middleton, near Manchester, on May 31st. The large room, lent free of charge by the corporation, was tastefully decorated with foliage plants and Orchids, lent by Mr. Alderman Halliday and Mr. J. W. Bentley. The show of Tulips was not up to the standard of late years. The wretched weather experienced in May prevented the development of flowers grown in late situations, consequently some exhibitors did not turn up at all, and others could only show very young flowers, which, as the day was cold and sunless, refused to expand, and were therefore relegated by the judges to low positions. Messrs. Needham, Prescott, and Horner, however, staged blooms which were fully grown and of excellent quality, and the first-named fully deserved his commanding position. Flamed flowers were especially well shown, especially that fine bizarre Samuel Barlow, which triumphed over Sir J. Paxton, which has held undisputed first place for forty years. Aglaia and Triomphe Royale were in fine form, while Annie M'Gregor, shown by Mr. Prescott, was well nigh perfect. Talisman and Chancellor were the best among the byblœmens, and old Duchess of Sutherland was in good form. Feathered dowers were not good with the exception of bizarres. Trip to Stockport, which obtained premier honours, did not deserve its place, the inner petals being half as long again as the outer ones. Breeders, with the exception of Mr. Horner's, were quite unworthy of a national show, being either weather marked or merely buds. There were not many novelties of note. Mr. Needham showed a fine newly broken feathered byblœmen, which he calls "Mary." Mr. Bentley had Charles H. Hopwood, heavy scarlet feather on a fine yellow ground, and Mr. Horner showed a few of his lovely breeder seedlings. When, however, one considers the wretched spring, the worst Tulip growers have experienced for many years, the wonder was, not that the flowers were below the average in numbers and quality, but that so many beautiful examples could be staged at all. The Judges were Messrs. Housley (Stockport), J. Woodhead (Stalybridge), and B. Simonite (Sheffield), and following is a complete list of their awards.

RECTIFIED TULIPS.

Class 1. *Twelve dissimilar Tulips, two feathered and two flamed in each class.*—First, Mr. C. W. Needham, Royton, with Samuel Barlow and Sir Joseph Paxton, flamed bizarres; Attraction and Wm. Wilson, feathered bizarres; Chancellor and Talisman, flamed byblœmens; Elizabeth Pegg and Trip to Stockport, feathered byblœmens; Mabel and Triomphe Royale, flamed roses; and Heroine and Julia Farnese, feathered roses. Second, Mr. A. Moorhouse, Wakefield, with Sir Joseph Paxton and Dr. Hardy, flamed bizarres; Sir Joseph Paxton and Wm. Annibal, feathered bizarres; Talisman and Lord Denman, flamed byblœmens; Trip to Stockport and Mrs. Hepworth, feathered byblœmens; Mary Jackson and Madame St. Arnaud, flamed roses; Modesty and Heroine, feathered roses. Third, Mr. J. W. Bentley, Middleton, with Sir Joseph Paxton and Samuel Barlow, flamed bizarres; Wm. Wilson and Charles H. Hopwood, feathered bizarres; Chancellor and Talisman, flamed byblœmens; Bessie and Guido, feathered byblœmens; Annie M'Gregor and Mabel, flamed roses; Alice and Mrs. Atkin, feathered roses.

Class 2. *Six dissimilar Tulips, one feathered and one flamed in each class.*—First, Mr. Needham, with Sir Joseph Paxton, flamed; Attraction, feathered; Talisman, flamed; Trip to Stockport, feathered; Mabel, flamed; and Heroine, feathered. Second, Mr. Bentley, with Samuel Barlow, flamed; Duke of Devonshire, feathered; Chancellor, flamed; Bessie, feathered; Annie M'Gregor, flamed; and Mrs. Atkin, feathered. Third, Mr. Mellor, Wakefield, with Lord Stanley, flamed; Sir Joseph Paxton, feathered; Talisman, flamed; Bessie, feathered; Mabel, flamed; and Alice, feathered. Fourth, Mr. Moorhouse, with Dr. Hardy, flamed; Sir Joseph Paxton, feathered; Bessie, flamed; Mrs. Hepworth, feathered; Mary Jackson, flamed; and Mrs. Lea, feathered. Fifth, Mr. Dymock, Stockport, with Sir Joseph Paxton, flamed; Sulphur, feathered; Lord Denman, flamed; King of the Universe, feathered; Annie M'Gregor, flamed; and Miss B. Coutts, feathered. Sixth, Mr. J. H. Wood, Middleton, with Sir Joseph Paxton, feathered and flamed; Lord Denman, flamed; Talisman, feathered; Mabel, flamed; and Heroine, feathered.

Class 3. *Six dissimilar Tulips, one feathered and one flamed (for small growers).*—First, Mr. W. Prescott, Bedford Leigh, with Sir Joseph Paxton, flamed; Lord Lilford, feathered; Talisman, flamed; E. Pegg, feathered; Annie M'Gregor, flamed; and Lea's Seedling, feathered (only one exhibit).

Class 4. *Three Feathered Tulips, one of each class.*—First, Mr. Needham, with Attraction, E. Pegg, and Julia Farnese. Second, Mr. Moorhouse, with Field Marshal, King of the Universe, and Modesty. Third, Mr. Prescott, with Lord Lilford, Mrs. Pickerill, and Modesty. Fourth, Mr. Mellor, with Lord F. Cavendish, Geo. Hardwick, and Lizzie. Fifth, Mr. Bentley, with Albert, Trip to Stockport, and Alice. Sixth, Mr. Wood, with Sir Joseph Paxton, Alice Grey, and Modesty.

Class 5. *Three flamed Tulips, one in each class.*—First, Rev. F. D. Horner, Burton-in-Lonsdale, with Samuel Barlow, Talisman, and Mabel. Second, Mr. Prescott, with Sir Joseph Paxton, Lord Denman, and A. M'Gregor. Third, Mr. Needham, with Sir Joseph Paxton, Talisman, and Mabel. Fourth, Mr. Bentley, with Samuel Barlow, Chancellor, and A. M'Gregor. Fifth, Mr. Mellor, with Dr. Hardy, Talisman, and A. M'Gregor. Sixth, Mr. Dymock, with Dr. Hardy, Talisman, and Mabel.

Class 6. *Two Tulips, one feathered and one flamed of any class, maiden growers only.*—First, Mr. G. Eyre, Ripley, Derby, with Sir Joseph Paxton and Duchess of Sutherland. Second, Mr. W. Mallinson, Middleton, with Mabel and Modesty. Third, Mr. T. Buckley, Stalybridge, with Sir Joseph Paxton and Modesty.

Class 7. *Two Tulips, one feathered and one flamed of any class.*—First (Samuel Barlow Memorial Prize), Mr. Needham, with Samuel Barlow and Mary. Second, Rev. F. D. Horner, with Sir Joseph Paxton and Modesty. Third, Mr. Prescott, with Sir Joseph Paxton and Lord F. Cavendish. Fourth,

Mr. Mellor, with Sir Joseph Paxton and Lord F. Cavendish. Fifth, Mr. Wood, with Prince of Wales and Bessie. Sixth, Mr. Bentley, with Samuel Barlow and William Annibal.

Class 8.—Single Blooms.—

Feathered Bizarres.

- 1 Mr. Prescott, with Lord Lilford
- 2 Mr. Needham, with Wm. Wilson
- 3 Mr. Needham, with Attraction
- 4 Mr. Prescott, with Lord Lilford
- 5 Mr. Needham, with Luke Ashmole
- 6 Mr. Mellor, with Lord F. Cavendish
- 7 Mr. Needham, with Richard Headly
- 8 Mr. Bentley, with Sulphur
- 9 Mr. Needham, with Rev. F. Symons
- 10 Mr. Bentley, with Sir Joseph Paxton

Feathered Roses.

- 1 Mr. Prescott, with Modesty
- 2 Mr. Needham, with Comte de Vergennes
- 3 Mr. Moorhouse, with Mrs. Lea
- 4 Mr. Moorhouse, with Modesty
- 5 Mr. Prescott, with Industry
- 6 Mr. Needham, with Heroine
- 7 Mr. Needham, with Annie M'Gregor
- 8 Mr. Bentley, with Rosetta
- 9 Mr. Bentley, with Julia Farnese
- 10 Mr. Bentley, with Alice

Flamed Byblœmens.

- 1 Mr. Bentley, with Adonis
- 2 Mr. Needham, with George Edward
- 3 Mr. Bentley, with King of the Universe
- 4 Mr. Horner, with Talisman
- 5 Mr. Bentley, with Duchess of Sutherland
- 6 Mr. Mellor, with George Hardwick
- 7 Mr. Bentley, with Headly's Seedling
- 8 Mr. Mellor, with Queen of the May
- 9 Mr. Bentley, with Friar Tuck
- 10 Mr. Moorhouse, with Bessie

Class 9. *Best feathered Tulip.*—Mr. Needham, with Trip to Stockport. *Best flamed Tulip.*—Rev. F. D. Horner, with Samuel Barlow.

BREEDER TULIPS.

Class 10. *Six dissimilar Tulips, two of each class.*—First, Rev. F. D. Horner, with Sir Joseph Paxton and seedling bizarres; Rosy Morn, and Lady Grosvenor, roses; Fairy Ring and Titania, byblœmens. Second, Mr. Needham, with Sir Joseph Paxton and Goldfinder, bizarres; A. M'Gregor and Madame St. Arnaud, roses; Adonis and Glory of Stakehill, byblœmens. Third, Mr. Wood, with Wm. Wilson and Sulphur, bizarres; Industry and Mabel, roses; Martin's 117 and Mrs. Cooper, byblœmens. Fourth, Mr. Mellor, with Sulphur and Sir Joseph Paxton, bizarres; A. M'Gregor and Rose Hill, roses; Geo. Hardwick and Adonis, byblœmens. Fifth, Mr. Moorhouse, with Sir Joseph Paxton and Lord F. Cavendish, bizarres; Mrs. Barlow and Mabel, roses; Bridesmaid and Geo. Hardwick, byblœmens. Sixth, Mr. Bentley, with Lloyd's 47 and Goldfinder, bizarres; Mabel and Rose Hill, roses; Glory of Stakehill and Alice Grey, byblœmens.

Class 11. *Three Tulips, one of each class.*—First, Rev. F. D. Horner, with Sir Joseph Paxton, A. M'Gregor, and Seedling; second, Mr. Needham, with Lloyd's Seedling, Madame St. Arnaud, and Sir Joseph Paxton; third, Mr. Wood, with Wm. Wilson, Rose Hill, and Alice Grey; fourth, Mr. Moorhouse, with Sir Joseph Paxton, Mabel, and Geo. Hardwick; fifth, Mr. Mellor, with Sir Joseph Paxton, A. M'Gregor, and Talisman; sixth, Mr. Prescott, with Sir Joseph Paxton, Mrs. Collier, and Janette; seventh, Mr. Dymock, with Dr. Hardy, Mrs. Moores, and Adonis; eighth, Mr. Bentley, with Sir Joseph Paxton, Mrs. Barlow, and Talisman.

Class 12. Single Blooms.—

Bizarre Breeders.

- 1 Mr. Prescott, with W. Wilson
- 2 Mr. Prescott, with Sir J. Paxton
- 3 Mr. Mellor, with W. Wilson
- 4 Mr. Bentley, with Goldfinder
- 5 Mr. Wood, with Sulphur
- 6 Mr. Mellor, with Lord F. Cavendish
- 7 Mr. Mellor, with Richard Yates
- 8 Mr. Horner, with Seedling

Rose Breeders.

- 1 Mr. Prescott, with Mrs. Collier
- 2 Mr. Horner, with A. M'Gregor
- 3 Mr. Moorhouse, with Mrs. Barlow
- 4 Mr. Moorhouse, with Mabel
- 5 Mr. Mellor, with Mdm. St. Arnaud
- 6 Mr. Bentley, with Queen of England
- 7 Mr. Mellor, with Industry
- 8 Mr. Bentley, with Olivia

Byblœmen Breeders.

- 1 Mr. Horner, with Seedling
- 2 Mr. Horner, with Seedling
- 3 Mr. Bentley, with Ashmole's 114
- 4 Mr. Mellor, with Hepworth's Seedling
- 5 Mr. Moorhouse, with George Hardwick
- 6 Mr. Eyre, with Talisman
- 7 Mr. Moorhouse, with Bridesmaid
- 8 Mr. Moorhouse, with Ashmole's 126

Class 13. *Best Breeder in the Show.*—Rev. F. D. Horner, with Fairy Ring.—J. W. B.

BUTLEY TULIP SOCIETY.

THE seventy-third annual Show was held at Butley, near Macclesfield, on Saturday, June 2nd. There were not as many flowers exhibited as last year, owing to the unfavourable weather experienced during the last month. As at the National Show, Mr. C. W. Needham was in great form, and took the lion's share of the prizes. The flowers shown were very good in quality except the breeders, which were not up to the usual standard. The principal prize at Butley is a silver cup given for the best stand of six rectified flowers. It was won by Mr. Needham with well grown examples of Sir J. Paxton, Mabel, Talisman, flamed; William Annibal, Heroine, and Mary, feathered. Mr. J. W. Bentley was second with Sir Joseph Paxton, Annie M'Gregor, King of the Universe, flamed; William Wilson, Mrs. Atkin, and Guido, feathered. The Judges were Messrs. H. and J. Housley of Stockport, and the following is a list of the awards:—

Feathered Bizarres.

- 1 Mr. Needham, with Attraction
- 2 Mr. Bentley, with Charles H. Hopwood
- 3 Mr. Jones, with Sir Joseph Paxton
- 4 Mr. Needham, with Typo
- 5 Mr. Needham, with Attraction
- 6 Mr. Dymock, with Sulphur
- 7 Mr. Needham, with William Wilson
- 8 Mr. Needham, with James M'Intosh
- 9 Mr. Needham, with Luke Ashmole

Feathered Roses.

- 1 Mr. Needham, with Heroine
- 2 Mr. Needham, with Mrs. Atkin
- 3 Mr. Needham, with Annie M'Gregor
- 4 Mr. Needham, with Comte de Vergennes
- 5 Mr. Needham, with Lizzie
- 6 Mr. Bentley, with Alice
- 7 Mr. Needham, with Heroine
- 8 Mr. Needham, with Julia Farnese
- 9 Mr. Needham, with Mrs. Collier

Flamed Byblæmens.

- 1 Mr. Bentley, with Talisman
- 2 Mr. Bentley, with King of the Universe
- 3 Mr. Bentley, with Talisman
- 4 Mr. Needham, with Adonis
- 5 Mr. Bentley, with Duchess of Sutherland
- 6 Mr. Bentley, with Chancellor
- 7 Mr. Dymock, with Lord Denman
- 8 Mr. Hague, with Queen of the May
- 9 Mr. Dymock, with Beauty of Litchurch

Three breeder Tulips, one of each class.—First, Mr. Hague, with John Wilkinson, Mrs. Barlow, and Alice Grey. Second, Mr. Bentley, with Goldfinder, Mabel, and Glory of Stakehill. Third, Mr. Needham, with Sir Joseph Paxton, Mabel, and Beauty of Litchurch.

Bizarre Breeders.

- 1 Mr. Needham, with Sir Joseph Paxton
- 2 Mr. Bentley, with Goldfinder
- 3 Mr. Jones, with Sulphur
- 4 Mr. Hague, with Wm. Wilson
- 5 Mr. Bentley, with Lloyd's 47

Rose Breeders.

- 1 Mr. Needham, with Annie M'Gregor
- 2 Mr. Bentley, with Mabel
- 3 Mr. Needham, with Rose Hill
- 4 Mr. Bentley, with Mrs. Barlow
- 5 Mr. Hague, with Lady Grosvenor

Mr. Needham won the prizes for premier feather and flame with Trip to Stockport and Samuel Barlow, and Mr. Hague the premier breeder with John Wilkinson.—J. W. B.

THE YOUNG GARDENERS' DOMAIN.

CLEAN versus DIRTY POTS.

I HAVE no desire to either advocate lazy ways or dirty habits, but during my short career I have found that *clean pots*, however preferable, are not absolutely essential to the well-being or healthy growth of a plant. I well remember my old copybook phrase, Cleanliness is next to godliness, and admit of its being applicable to both plants and people. Mr. Buchanan will doubtless be able to defend his own assertions, not requiring any assistance from me; but I notice that (page 340) he says, "Begin early to practise your brain in scheming and planning the easiest, the quickest, and the cheapest way to do a given piece of work." I am of the opinion that the quickest and cheapest way is not in fetching a man from a more important job, on a busy spring morning, to wash 6-inch pots to shift Tomato plants into. I have noticed, too, the ease with which some plants turn out of their pots with roots intact, and the difficulty in knocking out others, and attribute the latter, in many cases, to the plants having been placed in pots that were not properly dry, after washing. When the pots had been rubbed round inside with an old dry brush before crocking rarely have I found any difficulty in turning out the plants.

A worthy man under whom I formerly served used often to give me an injunction—viz., to regard the plants under my charge as little children, and minister to their requirements accordingly. Place before a hungry but dirty boy some soap and a penny bun, and I fancy all will agree that it is the latter he will operate upon first. I am afraid when I have complete charge I shall choose the lesser evil, and not let my plants go hungry because I have not the requisite number of clean pots to give them additional food in. In conclusion, I may say that I have had a taste of pot-washing this last week, but it is not while writhing under the back-ache that I am penning these, my first few lines, to the "Domain."—A YOUNG BOY, *Cheshire*.

CAMPANULA PYRAMIDALIS.

THIS is one of the most useful and stately plants for the decoration of the conservatory with which I am acquainted. To bring it to perfection I recommend it to be grown in the following manner:—Sow the seeds thinly in well-drained pans filled with light sandy soil the first week in June, placing the pans in gentle heat. When the seedlings are large enough place them singly in thumb pots, using similar compost, and arrange them on a shelf near the glass in a cool house. Admit abundance of air, and shade during bright sunshine. When the soil has become permeated with roots repot, and keep the plants somewhat close in a cold frame for about ten days, after which the lights should be used only as a protection against heavy rains.

By September the plants will require 6-inch pots, these being suitable in which to winter them. Assign them a position in the reserve garden, plunging the pots, just cover the rims with coal ashes as a protection against severe frosts. In February of the following year give the plants a final shift into 10-inch pots, using a rough compost, consisting of rich turfy loam with a little Mushroom bed refuse added, and enough sand to keep the whole porous. Care must be exercised in potting, in order to avoid breaking the lower leaves, which are very brittle. At this stage a few of the plants may be housed at once, but the major portion will be best removed to a cold frame for about three weeks, admitting abundance of air, and finally placing the plants in lines in an open position out of doors on a thick bed of ashes. Stake the plants with neat bamboos, fixing them to a stout wire attached to uprights at each end of the row.

Apply water carefully at first, and syringe during bright afternoons to keep down red spider. Weak liquid manure, after the pots are filled with roots, will assist in building up strong spikes of bloom. As the flower buds appear remove the plants to a cool house to develop their flowers before placing them in the conservatory or mansion. By adopting cool treatment from the first, strong healthy specimens will be insured, that will produce from three to six spikes of flowers, each 4 to 6 feet in height. These will be a mass of bloom from July to September, provided the old flowers be removed as soon as they have passed their best. From their pyramidal habit of growth (as the name implies) these plants form useful objects for dotting among groups of flowering plants or Palms, and in such a position their beauty, especially that of the white form, *C. p. alba*, is seen to advantage.—T. P.

THE CULTURE OF MUSHROOMS.

CONSIDERING the number of gardens in which Mushrooms are poorly grown, no one need be surprised that many young craftsmen have hazy ideas on their culture. To those of the "Young Gardeners' Domain" who have not the opportunity of gaining good practical knowledge on the subject I hope the following notes will be of service.

There is no production of the garden which is more highly valued in most establishments than Mushrooms. To obtain them all the year round artificial heat must be employed from the beginning of October until the end of April, but through the summer they can be successfully grown outside or in a cool shed. Material for making the beds is of much less importance than the structure. The ideal Mushroom house, in my opinion, is one having a central pathway, and a bed on each side about 4 feet wide and 3 feet 6 inches deep. About 4 feet above a second can be built of the same dimensions as the lower one; in this way two rows of beds on each side of the pathway can be arranged. The house must be heated with hot-water pipes suitably arranged, and the temperature must be about 60°, never much less, or more.

The next item to be considered is the material and the proper way to form a bed. I have heard of men growing Mushrooms in a mixture of turf, leaves, and horse droppings, with excellent results. But where droppings can be obtained there is nothing to excel them for producing large crops. They should be moderately dry before being used, but not too dry, or a large proportion of their valuable matter will be lost. Experience will recognise when they are in proper condition, and also the time to make them into a bed. Firmness is one condition of success both inside and out. If the material is put together loosely the heat will soon escape, and Mushrooms will not be produced long after it has left the bed. All the material should be placed in the bed at once and rammed and trodden down firmly. In a short time the temperature will rise perhaps to 100° or more, but the spawn should not be inserted until it falls to about 80°.

It is most important that good spawn be selected, as if it is poor no amount of after skill will produce first-class Mushrooms. The ordinary sized bricks should be broken into about a dozen pieces, and these placed singly, 3 inches deep, about 9 inches apart all over the bed. The holes made in doing this will let out some heat, thus bringing the temperature to the proper level; but they must not be allowed to remain open or heat will rapidly escape, and the spawn will not run if the bed is at all cold. As soon as the bed is spawned it should be cased with

loam, but if this cannot be spared any ordinary soil will do. It should be put on about 3 inches thick, and beaten down firmly with a spade till it has a smooth surface. If it is too dry for levelling it must be watered. To maintain a constant supply a bed should be made about every month. Worms and slugs occasionally attack Mushrooms, but a sprinkling of salt will effectually stop them, and otherwise act beneficially.

Outside beds ought to be made in the same way as inside ones in the matter of material and firmness. Form ridges about 2 feet 6 inches through, and 6 inches less in height, after they have sunk. They should be covered with long litter or straw, which will help to keep the heat and moisture in, and will protect the bed.

Many recipes are known for the making of spawn, but I will only quote one. Horse droppings one part, cow manure one-fourth, and loam one-twentieth. These are incorporated with stable drainings until the mixture is the thickness of mortar. When it is fairly set it is cut into squares, and about an inch of good spawn is dibbled in them. This is the white substance that can be found in hotbeds or cattle sheds, and is easily distinguished by its true Mushroom smell. The bricks are afterwards placed on a hotbed of about 60°, and the spawn soon fills them. When this has been done they are removed into a dark place, and allowed to become perfectly dry until required for use.—S. S.

FRUIT FORCING.

Cucumbers.—When the night temperature can be prevented from falling below 65°, artificial heat may be dispensed with, making the most of sun heat by early closing. Look over the plants twice a week, well thinning the old growths, and supply liquid manure occasionally. Syringe only in the afternoon, but damp in the morning and through the day, so as to maintain ample moisture in the house. With the ends of the structures north and south a slight shade becomes necessary, or from 4 to 5 in the afternoon when there is danger of the foliage being scorched. Pits and frames should be closed at 3 to 4 P.M., assisting plants in bearing with liquid manure. Remove bad leaves, cut out exhausted and too close growths, and stop young shoots one or two joints beyond the fruit. Where plants are enfeebled by bearing top-dress with lumpy loam, and layer some of the younger growths at a joint, from which roots will be emitted and strengthen the succeeding growths. Night coverings will not now be necessary, but it is important to attend to the ventilation early.

Vines.—*In Pots for Early Forcing.*—Stop the canes when from 6 to 8 feet long, pinching the laterals and sub-laterals at one joint as produced. This applies to cut-backs and to those from eyes started early and shifted into the fruiting pots. The smaller canes intended for planting need not be given more than 6 or 7-inch pots, as good fibrous roots are of more importance than luxuriant canes.

Vines Cleared of their Crops.—Syringe occasionally to keep the foliage clean, afford water to render the soil moist, mulch the border with short, spent material, and thus prevent the surface cracking, whilst encouraging the roots to work at the upper part of the border. Allow a moderate extension of the laterals, and admit air freely above 60°. There is no fear of the wood not ripening, and the difficulty is to prevent its doing so prematurely.

Houses of Ripe Grapes.—Black Hamburgs, and also Buckland Sweetwater, will be the better for a slight shade from powerful sun. A double thickness of herring nets will mostly be sufficient shade, and a good spread of foliage will assist the Grapes in keeping their colour. Moderate ventilation at all times, and free in bright weather, will prevent injury from moisture. Keep the laterals fairly under, but a little extension will assist in the retention of the principal leaves, and upon their continuance in health depends the maturity of the buds for the next year's crop.

Grapes Ripening.—When the Grapes begin changing colour admit a little air constantly, with sufficient heat in the pipes to maintain a night temperature of 65° and 70° to 75° by day, with 80° to 85° or 90° through the day from sun heat. Avoid an arid atmosphere, damping occasionally and do not allow the border to become dry. Vines ripening heavy crops will be assisted in perfecting them and storing nutriment for the future by an application of tepid liquid manure, or a top-dressing of fertiliser washed in. A light mulching of dry spent material will assist the Vines by securing uniform moisture. It is a stagnant atmosphere that does most of the mischief in Grapes spotting, and oftentimes in cracking.

Thinning Late Grapes.—There must be no delay in thinning the berries and bunches. Thin well to secure large and highly finished berries, leaving those of the large berried varieties, such as Gros Colman, about an inch apart, the oval-berried varieties not requiring so much room as the round ones. All should be so thinned that they will have space for swelling fully without wedging, and yet be so close that when dished they will retain their form. A pound of Grapes per foot run of rod is usually as many as Vines ordinarily finish well; therefore reduce the bunches so as to give about that weight, and if error is made let it be on the safe side, as Vines that are overcropped never finish their fruit well, and the Grapes are inferior in quality and keeping properties.

Regulating the Growths.—All foliage that can have full exposure to light should be allowed, but when the space is nearly covered with leaves keep the growths closely pinched. The foliage should be rather thinner in the case of white Grapes than in black—this more particularly applies to Muscats, which require high elaboration of the sap to insure their assuming a rich golden amber colour. Avoid large reductions of foliage at a time, it only tends to cause shanking through the check given to the roots. Keep the growths tied down from the glass, and so prevent scorching. Vines extending must be allowed to make as much lateral growth as practicable, but never permit them to interfere with the principal leaves. The laterals from the bearing shoots having been stopped at the first joint they may be allowed to ramble afterwards, subject to their not interfering with the main leaves.

Watering.—Inside borders must be properly supplied with water, following, in the case of Vines carrying a full crop and in vigorous but not luxuriant health, with liquid manure, or a top-dressing of fertiliser washed in and mulched with a little sweetened material to keep the surface moist and attract the roots. Outside borders may only need a light mulch, as the recent rains have made them moist enough, but if dry a proper supply of liquid manure should be given whenever necessary.

Temperature and Ventilation.—All late Grapes thrive in a high temperature with abundant nourishment at the roots and genial moisture in the atmosphere. Maintain a night temperature of 65°, and 70° to 75° by day in dull weather. Admit air early, and allow a little at the top of the house constantly, increasing the ventilation with the temperature, advancing to 85° or 90° from sun heat, at which keep through the day, reducing with the declining sun. Close at 85°, damping the paths then, and again before nightfall. It is well to close for a short time and then admit a little air, so as to prevent a vitiated atmosphere and allow of pent-up moisture escaping. Avoid cold draughts or sudden depressions of temperature, as they cause rust and favour the spread of mildew.

HOW TO OBTAIN A SURPLUS.

THE majority of bee-keepers are anxious to obtain a surplus from their bees in some form or the other, but how to arrive at the desired end is the difficulty we all have to contend with. Many things have to be taken into consideration, the chief in this country being the weather. Were it possible to have the bright sunshine and cloudless skies, such as are experienced in some other countries, for several days or, it may be, weeks in succession, when required during the honey flow, we believe there would be no difficulty in obtaining as large a surplus, and honey of much better quality, than could be obtained elsewhere.

It is, however, with uncertainties that we have to contend, and whether the season is likely to be good or bad we must make careful preparation beforehand. If the chief honey harvest is obtained from White Clover, by knowing the date it is usually in bloom, we shall find the last week in June and the first fortnight in July may be depended on when it is found at its best for honey production. In the South it will probably be a week or more earlier, and in the North a few days later.

The secret of obtaining a surplus is to have all stocks intended for honey production crowded with bees, and it is for bee-keepers individually to make up their minds how this shall be done. Those who have numerous stocks will always find some of their colonies increase at a much greater rate than others, although all may have had the same treatment. This fact is observed more in the spring than at any other season. If such is the case, it shows how useless it is to expect the same weight of honey from all the colonies in an apiary. It is therefore advisable for the bee-keeper to make a given number of stocks extra strong by adding bees, which will mix readily at this season if the middle of a fine day be chosen. But as this system has been mentioned on several occasions in these pages, it is unnecessary to enter into details now. We are convinced that a greater surplus can be obtained from a given number of hives, if worked on these lines, than from any other.

There are various ways of doing it. Some bee-keepers prefer two queens in a hive, and allow the bees from the two stocks to unite in the super. It amounts to the same thing. Two or more queens will supply the workers, and it is certainly an advantage to have an extra supply of workers on hand when required, as unity is strength when a surplus is required.

WORKING FOR COMB HONEY.

In some districts honey in the comb finds a ready sale, and bee-keepers are often anxious to obtain a few superior samples. Already we have seen some nicely filled much earlier than usual from the fruit blossoms and the Sycamore, but the bees were in a favoured spot. It is an advantage when using the ordinary 1 lb. section to have a few fully drawn-out combs placed in the centre of the crate, as

the bees will often work more readily in these at the commencement of the season than they will on foundation. In either case it is necessary to cover the crate up warm, as warmth is essential to the proper sealing over of the combs.

If the weather is warm and likely to remain so, a second crate of sections may be placed underneath the other when it is three parts sealed over; this will prevent the bees swarming, and they will continue storing a surplus whilst sealing over the combs in those already filled.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Stocks for Producing Flowers for Cutting in the Spring (A. G. G.).—The Brompton, the Cocardeau or Giant Cape, and the East Lothian are all suitable for the purpose, but are injured, if not killed, during severe winters unless grown in specially favourable positions. For growing in pots, and wintered in frames, East Lothians are very fine. If you only wish to try one kind, let it be the Brompton. If you want particular colours they must be ordered, the scarlet and white being the most in demand.

Caterpillar on Euonymus (R. H. R.).—The caterpillar with the gay colouring and looping gait is that of the magpie moth (*Abraxas grossulariata*), and that on the under side of the leaf, and with light threads attaching it to the surface, is another of the same species about to pass into the chrysalis state, which is done in a light cocoon. The moth emerges about the middle of summer. The caterpillar usually feeds on the leafage of Currant and Gooseberry bushes, also rosaceous plants, not on Euonymus, and the leaves sent do not appear eaten, the caterpillars having no doubt selected the shrub for purposes of pupation. The caterpillars are easily destroyed by hand-picking, as they are seldom very numerous.

Richardia æthiopica (Wakopa).—The above is the correct name of the plant that is so extensively, and often profitably, grown, by the sale of its large white spathes. It is a native of Africa, and known also as *Calla africana*—popularly, as the Arum Lily, though it is not a Lily, but an Aroid. Since writing your letter you may have seen the excellent article on the culture of "Arum Lilies," by Mr. Brotherston, on page 482. Thousands of plants are planted in rich soil in the open ground in May or June to be taken up and planted under glass in the autumn, though some growers prefer flowering them in pots. After flowering, the plants are removed and a crop of Tomatoes or Cucumbers obtained in the house before it is wanted for the "Arums" in the autumn. The plants are not bulbous, but herbaceous perennials.

Pears Infested with Maggots (C. C. E.).—The Pears are attacked by the Pear midge larvæ. The subject was fully treated in the *Journal of Horticulture* of June 3rd, 1897, page 487, and illustrations given of the pest—the Pear gall gnat (*Diplosis pyrivora*). The only thing to be done now is to remove all the swollen fruits and burn them. This must be done at once, or the pests will leave the fruit and become pupa in the soil. A dressing of kainit in the autumn, 4 ozs. per square yard, has a good effect, but the midges come from neglected orchards, so only continued action can completely eradicate the pest. Instead of committing suicide, if the wash advised kills your trees, we would suggest the alternative of your giving the adviser of it a horsewhipping. We trust the fresh lease of literary life you have taken will prove long and satisfactory, and when the pen needs exercise let it have a run; the course is as safe as ever.

Compost for Eucharis (Meath).—The soil should consist of two parts rich turfy loam to one of leaf mould or thoroughly decayed manure, with about a sixth of broken charcoal, to keep it open, incorporating all well together. Liquid manure may be given with advantage when the plants have got well hold of the soil, and the pots crowded with roots, especially after the flower scapes appear.

Daphne indica rubra (Idem).—This plant requires a greenhouse temperature, and cannot be grown in too much light after established from the cuttings or grafts. When making growth a temperature of about 55° is suitable, but the plants may be subsequently grown in a frame. They require gradually but well hardening afterwards, and keeping quite cool during the autumn and winter, in order to thoroughly ripen the wood, as on that depends the success in flowering. Avoid overpotting. A suitable compost consists of equal parts peat and loam, or the latter alone when of a turfy nature. Give water very carefully, especially in winter. Good drainage is essential to the health of the plants.

Overgrown Stephanotis (S. B.).—When the plant has filled the allotted space it is advisable to thin out the longest and barest of the branches in such manner as to keep the plant well furnished with young growths from base to extremity, having the flowering parts so far asunder that light and air can act upon them. This requires a little forethought, and then it is easy to secure a succession of flowering growths by cutting back the long and bare wood, or thinning as required. The plant will give much finer flowers than by reserving a large quantity of wood, which is useless, because much of it will be bare of flowering parts. The plant should be kept rather dry a few days before and after any extensive pruning, but not so dry as to injure it.

Plants and Insect (J. C. S.).—*Brunfelsia* (*Franciscea*) *Hopeana* or *confertiflora* is a stove plant and very floriferous, succeeding in a cool stove or warm greenhouse, if kept rather dry in winter, but not causing the leaves to fall. *Dasyliion longifolium* is an ornamental greenhouse evergreen, admirable for conservatory decoration, also for sub-tropical gardening. *Magnolia Soulangeana* is probably a natural hybrid between *M. conspicua* and *M. obovata*, white with purple tint, hardly so sweet as those referred to, yet a fine form of *M. conspicua*. The lively and beautiful insect is the Box sucker (*Psylla buxi*), which injures the young shoots and leaves, causing them to have a crumpled and stunted appearance. It seldom, however, does much harm. The bushes may be syringed with any of the advertised insecticides, following the instructions.

Pear Leaves Blackened (J. M.).—The leaves and young wood are badly attacked by the scab fungus (*Fusicladium dendriticum*) in the early leaf and shoot form, and may probably have been accelerated by the recent wet, followed by the current cold, dull weather. It is rather common this season on various rosaceous plants, especially Thorns and Pears, and is known as *Actinonema Cratægi*. We should cut away as much of the growth as can be spared, also any young fruits affected, as they would only crack if left, then spray the tree with a solution of sulphide of potassium (liver of sulphur) $\frac{1}{2}$ oz. to a gallon of water. If you have not a spraying apparatus apply by means of a fine-rose syringe, repeating in about ten days, and again at a similar interval. In the autumn it would be advisable to lift the tree, or at least to root-prune to some extent, and add fresh soil with calcareous matter, such as old mortar rubbish.

Roses for Pots (P. N.).—We have raised many Roses from cuttings, choosing firm, healthy portions of matured wood of the current season with dormant buds. The stems which have flowered in the summer, taken with a heel or otherwise, cut about 8 inches long, inserted 6 or 7 inches deep in sandy soil in the open ground early in October, have given us a good proportion of plants, as also have firm short-jointed portions of shoots which have not flowered. If the leaves which rest on the soil when the cuttings are inserted can be kept fresh by shading and sprinkling as may be needed rooting is the more sure, though we have raised hundreds of plants by inserting the cuttings a little later, or as soon as the leaves can be shaken off. The method was to stretch a line, chop out a trench of the proper depth, throw some sand in it, press down the cuttings slantingly about 6 inches apart, place back the soil and tread it against them, with the tops just above the level of the soil. All varieties do not emit roots with equal freedom. Well selected cuttings of the common Briar, made and inserted in the same way when the leaves are falling, give a good percentage of plants which remain in position, and are suitable for budding with any varieties of Tea, H.P., or other Roses during the second summer after insertion. When they are ready the soil is cleared from around them for the insertion of one bud in each stem—the part previously within the surface of the ground. The stocks are cleared of basal growths for facilitating the operation, but are not cut down till the following spring, when the bud extends and, in the case of many varieties, flowers the same season. These "maidens," if taken up and either potted or planted in the autumn and cut back in the spring, make good flowering plants. The pots containing the Roses are plunged to their rims in ashes in summer, and if they remain out through the winter the rims are well covered also, or there would be many breakages. When a stock is once obtained it is easy to maintain or increase it by raising the desired number of plants yearly. You must remember that all the buds must be cut clean out the Briar stems, except a couple at the top, and which are just above ground when the cuttings are inserted; but the whole of the buds may be left intact when the cuttings are taken from varieties of Roses that you may desire to increase by that method. We are glad that after many years of reading it you find the *Journal* as acceptable as ever, and trust it may be so for many years to come.

Peach Leaves Falling (*D. H.*).—The specimens arrived as we are preparing for press, and cannot possibly be examined this week. They shall have attention.

Browned Leaves on Cordon Apple Trees (*J. B. W.*).—The leaves are rusted and browned by the larvæ of the small ermine moth (*Hyponomeuta padellus*), which live in small webs, shifting their quarters and enlarging the "nests" as circumstances of food requirements and increase of growth occasion. The simplest method of riddance is to take the "nest" boldly in the hand and thoroughly squeeze the mass of caterpillars. This can very easily be carried out on cordon trees; or if you do not like the procedure, thoroughly syringe with petroleum emulsion solution, using such force as to break up the web-nest. As there appear other pests at work you may follow with a spraying of Paris green mixture, 1 oz. of paste to 20 gallons of water, which should be so applied as to simply coat the foliage with a thin film, keeping the liquid well agitated during its use.

Pear Shoots Eaten (*R. G.*).—The softsoap and quassia preparation has not killed the yellow thrips. There were plenty of them on the specimen, and they succumbed in "no time" to a solution of aniline, one part in twenty parts water, this being, perhaps, the best thripsicide. The thrips are the yellow species (*Thrips cerealium*), usually found on corn and grasses, but not uncommon on broad-leaved plants, especially the Lesser Bind-weed (*Convolvulus arvensis*). They, however, have not eaten the leaves, this damage being caused by some caterpillar, which we did not find. The creature usually folds the growing points of the shoots together, or rather the leaves of the respective shoots attacked, sometimes eating out the "hearts," and not unfrequently the flowering parts. The most common delinquent is the caterpillar of the lesser Apple-leaf roller moth (*Teras minuta*), but there are several species, and all injurious in nurseries and fruit plantations. The eggs are laid in the spring on the unfolding buds or leaves, the larvæ soon hatching to devour the tender foliage or floral parts, some of which they roll into a protective covering. They continue feeding for about a month, when they pupate within the folded leaves, or seek dry quarters, and a week or so later emerge as small reddish grey moths. There are two or three broods in a season of some species. The common sparrow (*Passer domesticus*) is very fond of the caterpillars, so also are chaffinches and the warblers for feeding their young. On low trees the best cure is hand-picking, and on tall spraying early with Paris green paste, 1 oz. to 20 gallons of water. For the thrips use a solution of petroleum emulsion, following the instructions, or any of the advertised insecticides, these having a deterring effect on the moths. Tobacco juice diluted to a safe strength has a destructive effect on thrips, and kills or prevents most insects from attacking the growths of plants or trees.

Odontoglossum Leaves Spotted (*H. W.*).—The leaves have a very singular appearance when held to the light, the spots having brown centres and streaks in the yellow part traversed by some micro-organism, which has abstracted the contents of the tissues immediately beneath the cuticle, and given rise to the spotted appearance. The spots are not larger than pin-heads in some cases, not so large when first noticed, and become confluent, thus spotting the leaves in an irregular manner. At first the spots have whitish centres, but as they increase in size become brown with a somewhat broad yellowish surrounding ring. The only outgrowth or "fruit" found was that of an *Heterosporium*, closely related to *H. minutulum* (*Cooke and Massee*). It is very destructive to the leaves, and may probably be arrested by sponging the plants occasionally with a solution of sulphide of potassium (liver of sulphur), $\frac{1}{8}$ oz. to a quart of water, for the young leaves, and $\frac{1}{4}$ oz. to that amount of water for those fully developed. The strength last named would not probably hurt the young leaves, but it is advisable to err, if at all, on the safe side. The white marks on the leaves are caused by a minute species of red spider (*Tetranychus orcidis*) which has been charged with causing the spots, but its action more resembles that of thrips. It also succumbs to the sponging with sulphide of potassium solution. We may also mention that sulphate of copper (bluestone) solution has been used with good effect, 1 oz. to $1\frac{1}{2}$ gallon of water, applying carefully with a sponge to both surfaces of the leaves. We should have the plants repotted, and every means adopted to invigorate them. *Odontoglossums* require a moderately moist atmosphere, and, after a bright day, are much invigorated by a gentle dewing by means of a syringe. They are also much healthier and more floriferous when grown in a house where they can obtain all the light possible, short of the fierce sunlight of our summers.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Farnham*).—*Ilex aquifolium angustifolium*. (*J. L. S.*).—1, *Adiantum concinnum*; 2, *Zephyranthes carinata*; 3, *Billbergia nutans*. (*F. M. O.*).—1, *Calampelis* (*Eccremocarpus*) *scaber*. (*W. Y.*).—1, *Woodwardia radicans*; 2, *Lastrea Filix-mas*; 3, *Todea*

superba; 4, *Pteris serrulata*; 5, *Asparagus plumosus nanus*; 6, *Adiantum Pacotti*. (*B. P.*).—1, *Cypripedium barbatum*; 2, *Oncidium sphacelatum*. (*H. C.*).—1, *Acer platanoides*; 2, *Choisya ternata*. (*M. H. S.*).—Possibly *Crataegus coccinea*. Cannot be certain about this without seeing fruit or flowers.

FIRST QUALITY.

YES, indeed! we pretend this is what we strive for, and without which we shall never be satisfied; but really, if we come to look at the subject seriously, how very few of us ever attain to "first quality" in what we do or make or produce. How soon we tire! one failure, perhaps, we look for, a second depresses, and a third overwhelms us, and we are glad to fall back into the old ruts, the old customs, and say, What was good for our fathers is enough for us. Mind, this is not true of us all, nor had it need be; but if we each ask ourselves the question, "Am I not too often content with only

achieving a measure of success instead of pressing on to perfection?" how many could honestly affirm that they were never transgressors?

The road to perfection is rough and stony, hard to travel, and wearisome to the feet; but the fact remains that there is a road, and the diligent surmount the difficulties and reap the reward. We have often spoken of the value of milk as an essential article of diet; but, like all other valuable products, it is most open to adulteration, and diluted adulteration is a punishable offence, and as such can be dealt with by the law.

But for all that, it is quite possible, and more than probable, that a milk customer (unless he always has milk from the same cow) might find on analysis that the feeding qualities of his pint varied with every day in the week—some days he would get full value for his 2d., other days very much less—and this not because the purveyor was a cheat, but simply because the milk from different cows will be found to vary in value most materially. Milk does not "flow" in this land as plentifully as it did in Canaan of old, and the dairy farmer has much anxious study to compile a dietary form for his cows which will enable him to meet the demands of his customers.

A cow in full milk is a very "tickle" animal; so many little things will throw her out of gear—a chill, a change of food, or a temporary ailment. As to a chill in this climate, how is such a check to be avoided? and also, how difficult it is all the year round to provide a sufficiency of succulent food that will not taint the milk! Who can guard against midsummer days cold as Christmas, or burning droughts that destroy everything green? It is indeed a science, the proper feeding of a dairy herd—the feeding that will make them produce the utmost extent of milk.

Then comes the quality of the milk. We all know the difference between the thin blueish gallons of a sturdy old Dutch vendor, and the rich thick pints produced by a little Jersey, and we know which we like best. It is quite possible to get good rich milk from almost any cow that walks, provided she is fed on fat-producing food. It is merely reducing the feeding art to a system. You cannot subtract 3 from 0; you must treat the cow as a machine, and by feeding her well and suitably she will take care that you see your outlay again.

On those farms where only few cows are kept, just to supply the house with butter and milk, it is advisable that quality rather than quantity be aimed at. It is so possible to feed milk cows that they are much readier for the butcher than for the milk pail—*i.e.*, the good rich food turns into body fat rather than into butter fat.

Some interesting experiments were conducted in Germany last years—experiments made with a view to testing the qualities various foods produced in the milk. Cows fed on hay alone produced richer (butter fat) milk than those which, in addition to the hay, received rations of carbohydrates, such as starch. The starchy matter probably went to make body fat. When, in addition to hay, oily food was given there was an immediate rise in the quantity of butter fat found in the milk. Sesame oil, linseed oil, and tallow stearine were made into emulsions the increase was as follows:—Linseed, 5.24 per cent. of fat; tallow stearine, 4.24 to 5.5 per cent.

The oily matter must be given in an easily digested form, or the end desired is defeated. We all know how difficult it is for some human stomachs to assimilate oily matter, and how soon the digestive organs are put out of tune, and it is just the same with the cow. An impaired digestion means loss of appetite, and loss of appetite means loss of milk-producing power. Palm and Cocoa-nut cake fat are also most useful as butter formers, and, of course, good linseed cakes—that is, cake out of which not all the oil has been pressed. Our oil pressers have become so clever that with modern machinery they leave us now a very dry cake. Then, again, it is possible to use too much cake, and the result would be a soft oily butter. Good nitrogenous and oily foods are necessary for the production of butter fat in milk.

Subjoined are some rations given to cows at the Midland Dairy Institute, with the view of testing the influence of food on the

production of butter fat in the milk. There were five cows in each lot:—

Lot A.—Roots, 50 lbs.; chaff, 10 lbs.; hay, 6 lbs.; bran, 2½ lbs.; beanmeal, 3 lbs.; oat and wheatmeal, 2 lbs., with 2½ linseed cake with 6.83 per cent. oil.

Lot B.—Same as A, with 4½ lbs. linseed cake of 16.83 per cent. oil.

Lot C.—Same as A, with 4½ lbs. linseed of 6.83 per cent.

Lot B produced most butter, but of low quality—*i.e.*, soft and oily, while that of Lot C was the best, the quantity being but very little below that of Lot B—0.89 as against 0.91. The cows of Lot B were in much better condition at the end of the tests than those of the other two lots.

WORK ON THE HOME FARM.

Warmth, real warmth at last! We have had three or four days of electricity with very heavy showers, and some of the land is in a state of puddle, but the temperature is now most satisfactory both night and day, and what we most fear is a period of burning sun heat, for the young Barley and Oats have become so accustomed to a liberal supply of liquid, and their roots are consequently so near the surface, that too sudden a change might be for the worse rather than the better.

Wheats are growing fast, and there will be a heavy crop of long straw; this is now assured, but it is too soon to forecast the yield of grain. Barley and Oats are improving, but, so far, under average, greatly so, in fact; forcing, stove-like weather, is required for these crops.

We have been hard at work hoeing, but the weather has not been favourable, and many weeds have again got a foothold; this means more expense, as the extra hoeing hands have to be kept on longer, but as regards Mangold and Potatoes much can be done with the skerry. Potatoes have grown so fast since our last that we have had to hurry up with the top-dressings, and earthing ploughs are busy at work; this crop is very backward, but is distinctly promising. Small tubers, the size of horse beans, have been observed by the men. Sheep are doing very well, lambs particularly so. So far there has been no trouble with the fly, but with greater warmth the maggots are sure to put in an appearance. Tobacco powder we have found to be the best preventive of a second attack by these pests.

Milk cows have a good pasture, and are yielding good supplies of milk. Butter at 8d. per lb., however, leaves no margin for profit, and we are rearing as many calves as possible, but good well-bred ones are not easy to meet with.

Hay crops are very good, and another week will see haymakers at work. Clovers were grazed rather late before being laid in for hay, but the wet season has been very favourable to them, and they are promising, though they will not be ready to cut much before July.

ROOK PIE.—Adverting to our note on page 492, last week, our agricultural correspondent writes:—"All we can say is that the man referred must have had a bad digestion or an indifferent cook. A well made pie will consist of rooks' breasts alone, which have been previously steeped twenty-four hours in milk and water. The rooks should be skinned, not plucked. Please note our address, and we will gladly take all surplus rooks—for ourselves, not for our dog." The case alluded to was not one of "digestion," but of dog *versus* man's judgment in eating rook. The man thought the dog knew the better, and followed his example in refusing to taste the young "craws." We still wonder if the farmer's dog is of the same opinion as his master, who seems ready to "take all surplus rooks." The italics are ours, but it is a "large order." The hints for making a rook pie are all the same useful.

REMARKS.

- 5th.—Warmer; occasional spots of rain in morning, and bright sun in afternoon.
 6th.—Sunny early; rain from 9.30 to 11 A.M., and showery till noon; gleams of sun in afternoon, and fine night.
 7th.—Bright sun almost throughout, but occasional cloud at midday.
 8th.—Overcast day, with a shower at 1 P.M.
 9th.—Overcast morning, with spots of rain; fair afternoon.
 10th.—Rainy in the small hours, and almost continuous rain from 7 A.M. to 1 P.M.; fair afternoon and sunny after 6 P.M.
 11th.—Almost cloudless throughout.
 Temperature rather above the average, rainfall still below it.—G. J. SYMONS.

edition, 216 pages, 2/6; post free, 2/10.—JONES and
ATTWOOD, Stourbridge.

NOTICE.—Don't stake your Carnations till you
have seen the Patent Improved Coil Stake. No
tying required; stakes last a lifetime. The greatest boon
ever offered to growers. Only wants seeing. 7 6 per 100;
sample dozen, 1/-, carriage paid. Cash with order.—
A. PORTER, Stone House, Maidstone.

DEFY THE BIRDS by Buying our Noted
ROTLESS TANNED NETTING, as supplied to the
Principal Gardeners in the Kingdom. Orders over 5/- value
are sent Carriage Paid. 100 yds. by 1 yd., 3/-; 200 yds. by
1 yd., 6/-; 300 yds. by 1 yd., 9/-. Can supply any length and
width.—UNIVERSAL SUPPLY ASSOCIATION, East
Street Works, Reading. (Name Paper.)

FOWLER'S MEALY BUG DESTROYER
effectually and instantly destroys this most trouble-
some pest without stain or injury to the foliage. In
bottles, 1/-, 2/6, 5/-. and 10/- each. Sold by all Seedsman.—
CORY & CO., Ltd., LONDON, E.C.

COTTAGE GARDENING; being an Essay to
which the Royal Horticultural Society awarded Mr.
W. EGERTON HUBBARD'S Prize, February 16th, 1870. By
E. W. BADGER. Third Edition. Price 3d.; post free, 3½d.—

CHAMBERS, FLEET STREET, E.C.

PURE WOOD CHARCOAL, Specially Prepared
for Horticultural use. Extract from the *Journal of*
Horticulture: "Charcoal is invaluable as a manurial agent;
each little piece is a pantry full of the good things of this
life. There is no cultivated plant which is not benefited by
having Charcoal applied to the soil in which it is rooted."
Apply for Pamphlet and Prices to the Manufacturers—
HIRST, BROOKE & HIRST, Ltd., Leeds.

GARDEN NETTING, small mesh, keep out the
smallest birds, oiled and dressed; will not rot if left
out in all weathers. 105 yds. by 1 yd. wide, 3/-; by 2 yds.
wide, 6/-; 105 by 3 yds. wide, 9/-, and so on to any width;
carriage paid on all orders over 5/-. As supplied to the
Royal Gardens. Commoner netting, 50 square yds. for 1/-.
I do not require Payment until you have received and approved
of the Netting.—From H. J. GASSON, Garden Netting
Works, Rye.

GREENHOUSES from £3 5/-; VINERIES,
CONSERVATORIES, FRAMES, SUMMER HOUSES, &c.
Illustrated List Free. Makers to H.M. THE QUEEN and
H.R.H. THE PRINCE OF WALES.

Journal of Horticulture.

THURSDAY, JUNE 23, 1898.

THE JOURNAL OF HORTICULTURE can be obtained
from the Office, 12, Mitre Court Chambers, Fleet St.
London, post free for a Quarter, 3/9. Editorial
communications must be addressed to 8, Rose
Hill Rd., Wandsworth, S.W.

IN ST. BRIGID'S GARDEN.

IN St. Brigid's garden St. Brigid is the gardener,
and employs her own means to the end of
that perennial enjoyment which has nought to do
in this case with broad acres or glass houses, and
to whom the world is indebted for that glorious
strain of garden Anemones. After leaving Dublin
by the coast railway, which has done so much for
travellers by it to show off one of the most
picturesque parts of picturesque Ireland, and robbed
many a marine residence of freedom to the fore-
shore, the run is but a short one to the quiet little
station of Ballybrack, close to which the imposing
rocky heights of Killiney tower up in bold relief.
Here the ordeal has to be faced—a few minutes'
uphill walking to find a lady, disappointed because
a distinguished amateur hardy plantsman was, from
no fault of his own, not at Ballybrack at the same
time as myself.

St. Brigid was "at home" expecting us, but it
was not quite the St. Brigid we had conjured up;
in fact she should have been, to use the lady's
own words, "an old woman in a poke bonnet;"
though it is less easy to understand how some
of her correspondents have erred in addressing
her as S. Brigid, Esq. The "little garden" proves
to be a *multum in parvo*, and as for its size,
the way in which St. Brigid tripped daintily from
bed to bush, and from bush to border, expatiating
upon beauty that had been, or glories to come,
with existent charms, leaves one delightfully in
doubt.

The handsome foliage of *Vitis Cœnnetiae* drapes
the porch under which two bushes of the Narrow-
leaved Myrtle flourish, not necessarily protected in
this Riviera-like climate, for others are to be seen
freely exposed at all seasons. There is just a
suspicion of orthodoxy present in some neatly
trimmed grass plots, beyond which imposing masses
of the large starry *Olearia* are in their glory; and
surely no greenhouse ever sheltered a finer specimen
of *Cytisus elegans* than is to be seen in the back-
ground. *C. Everestianus* is spoken highly of by
this enthusiastic lady gardener, but it has not yet
found its way into the "little garden."

Near the aforesaid trimly kept lawn Nature asserts its wild ways in an unkempt growth of Solomon's Seal, now in all its beauty of arching, glossy foliage, and pendant bells, beneath which again the wild Hyacinth flourishes at its own sweet will. Near at hand the bold, bronzy foliage of *Rogersia podophylla* is very assertive to the eye, and a leaf measured by the saintly umbrella first, and my tape afterwards, made a record of 36 inches across.

The "little garden" lies high and dry, and many of the lesser things are sheltered by the greater—hidden in fact; but those who hide know where to find, and the umbrella now acts as a divining rod to disclose a perfect plant of *Ramondia pyrenaica*, while *Primulas*, notably *rosea*, in the most luxuriant foliage, and a thousand plants have a foothold in or about rock-studded banks. One bank in particular is a galaxy of creeping, clinging, rambling plant life, and upon the crests of these mounds and banks bushes of the Gum Cistus are bristling with buds. *Aralias*, *Bamboos*, and others form a kind of maze, through which one wanders oblivious of time or space, as the enthusiastic guide leads the way.

How lovingly the Lady of the Anemones tells the story of some favourite plant, disclosing the hidden grace and beauty of its charms! The bond of sympathy betwixt her and them seems complete when some tangly plant clutches the cloak of some shimmering material, donned as a passing shower scudded by.

The kitchen garden, or what may have been so once, for the kitchen part is conspicuous by its absence, is entered by an archway of *Clematis montana grandiflora*. Here are breadths of countless *Narcissi* and borders of *Hellebores*. The unique single white *Pæony* is in strong force, with such plants on the walls as *Clinodendron Hookeri*, now gorgeously arrayed with long-stalked, pendant, crimson blooms. It is rare I suspect; who can tell us something about it? *Solanum jasmioides* grows rampantly along the top of the wall.

It is here, perhaps, in this portion of the "little garden" that St. Brigid's labours of love are most in evidence. Here are the Anemones bearing her name and fame, but not quite so happy as they were, I am told, at Howth on the opposite shores of "sweet Dublin bay," where the old strain of garden Anemone under her skilful hands yielded its handsome progeny. However, the good work is now going on with the Daffodils and with the *Hellebores*, the now declining foliage of the former measuring, in the case of some varieties, 40 inches in length, whilst of the latter a bed of baby seedlings, it is hoped, will speak for themselves later on.

Each season of the year has its own story to tell in the "little garden," the aim of its mistress being to have flowers all the year round, and this without a suspicion of glass or greenhouse; hence, as I said, the enjoyment is perennial. Noticeable among things noticed, and too numerous to mention, were Homer's white Rose, *Rubus deliciosus*, large bushes of *Salvia fulgens* (a speaking testimony of the climate), *Clianthus puniceus*, and a bush of the helmet *Calceolaria*, smothered in its quaintly pretty blossoms. A *Smilax* in particular is pointed to with pride, in spite of its nomenclature of *S. asparagoides retrofractus arboreus*.

Interesting, too, is *Drimys Winteri*, not merely as affording the "Winter Bark" of commerce, used for the same purposes as cinnamon, but because the plant was first brought to England from the Straits of Magellan in 1579 by Captain Winter, who went out with Sir Francis Drake in his voyage round the world.

Yet with all its interest, grace, and charms, comes a tale of woe from the "little garden." The ubiquitous slug is no respecter of persons or of plants. "Could I suggest a remedy?" "Oh! birds—blackbirds and thrushes." "But they can't eat them all." A thought crosses one's mind that the slugs might have been banished with the snakes and toads instead of fattening and battenning on these tender plants, then things would be nearly perfect. Nearly, not quite, perhaps, for over the tiniest of cups in the daintiest of drawing-rooms comes the faint echo of complaint in another direction, and this from one of the fraternity, for So-and-so grumbles he "can't grow his vegetables in

the shadow of the house," hence the reason, perhaps, there is no recollection of seeing any.

No pen of mine could do justice to the unique situation of St. Brigid's Home, from the front of which one looks over a valley to the mountains of Wicklow close at hand. Seascape on the left with Bray Head in the background, and immediately opposite sunshine chases the shadows over Lugnaquilla, the Sugarloaf, as the return is made to Ballybrack Station, with a bouquet culled from St. Brigid's garden.—K., Dublin.

ROUTINE IN MELON CULTURE.

WHEN the crop is over and the plants are healthy and not affected with red spider, they may be reserved for a second crop, in which case growth should have been retained and encouraged in the late stages of the first crop, and a good set of fruit secured on these, whilst the structures were kept drier for the fruit ripening. The old growths in this case should be cut clean away, but not all at once, as that would give a check, reserving the best of the growth, and any cuts that bleed should be dressed with quicklime.

Remove a little of the surface soil and supply some lumpy loam. Soak with tepid water, and follow at once with liquid manure. Mulch with horse droppings spread previously in a shed and turned over two or three times before using for the Melons. They are best given a little and often rather than a heavy mulching all at once. If kept moist the roots will soon spread in the loam. Thin the fruits, apportioning them to the vigour of the plants—half a dozen is a full crop, and overcropping fatal to quality.

REPLANTING IN HOUSES, PITS, AND FRAMES.—Where the plants are not in a condition to bear second crops clear them out at once, removing the soil. If the heat be supplied by fermenting materials, remove a portion of it and add some fresh, mixing it with the fresher portions of the old, which will revive the bottom heat sufficiently to give the young plants a start. Cleanse the house or structure thoroughly, success greatly depending on a good start. Plant on hillocks or ridges. Rather strong loam three parts, one part horse droppings, and one part old mortar rubbish, mixed and rammed firm, will grow Melons well. When warmed through plant carefully, shade from bright sun for a few days, ventilate early in the morning, and close early with a moist atmosphere.

PLANTS SETTING THE FRUIT.—With a sturdy, short-jointed, and not crowded growth, Melons set freely at this time of year, but air should be admitted so as to keep the pollen dry, and the atmosphere genial. Insects visit the flowers, and by pollen transference effect fertilisation. In moist weather, however, Melons do not set freely in frames; in that case apply good linings, and admit air freely, ventilating a little at night so as to prevent the deposition of moisture on the blossoms, as to be effective the pollen must be dry, and the stigmas not destroyed by moisture. Keep the foliage fairly thin, for without light and air a good set of fruit need not be expected. A free use of the knife is not desirable whilst the fruit is setting. Afford water only to prevent the leaves flagging, and keep it from the foliage.

PLANTS SWELLING THEIR CROPS.—When the fruit is the size of a hen's egg, add fresh soil to ridges or hillocks after a good watering. Syringe the plants in houses at closing time, and damp well down in the mornings and evenings of hot days. Afford liquid manure copiously, always weak and tepid, or sprinkle a little fertiliser on the surface and wash it in. Supply supports to the fruit in good time, placing slates under those in pits and frames. Keep the foliage fairly thin, not allowing a large amount to be made, and afterwards have to reduce it in quantity, for that gives a severe check, and may result in gumming. Ventilate at 75°, keeping the temperature through the day at 80° to 90° with sun, and close so as to raise it to 95° or 100°, with plenty of atmospheric moisture. In dull weather a little ventilation without lowering the temperature prevents the foliage becoming soft and unable to bear sun after such periods. Admitting a little air about 6 P.M. on days when the houses have been closed early, will allow the temperature to fall gradually, and any vitiated air to escape. As the fruit approaches ripening reduce the water at the roots, but not to the extent of causing the foliage to flag, and withhold water from the fruit. A gentle warmth in the pipes or linings to frames, with a little air constantly, afford the best safeguard against cracked fruit, which is mostly caused by a moist atmosphere at night, or a dull moist period following hot weather.—PRACTITIONER.

PARIS EXHIBITION OF 1900.—We are requested to state that the Royal Commission are now prepared to circulate information respecting the exhibition. The classification and rules for exhibitors, together with forms of application for space, can be obtained by applying to the Secretary of the Royal Commission, Paris Exhibition 1900, St. Stephen's House, Westminster, S.W.

* We do not see the name in the *Index Kewensis*. Is it "*Crinodendron*" syn. *Tricuspidaria Hookeriana*—a Chilean plant?

CATTLEYA MENDELI OAKES AMES.

THE named forms of *Cattleya Mendeli* become more and more numerous, and there can be little doubt that many do not deserve any distinctive appellation. Such a charge cannot, however, be laid against C. M. Oakes Ames, for it is one of the noblest varieties that has been exhibited, and attracted extraordinary attention at the Temple Show. The flowers are above the average size, are very substantial, and of remarkably rich colour. The broad, slightly waving petals are rich rose, with a bright crimson flame at the tips; the sepals are also rich rose. The handsome lip is velvety maroon crimson, the throat being yellow with crimson veins. As will be observed in the woodcut (fig. 98, page 521), the formation of the lip is very fine. It received a first-class certificate.

RESTREPIAS.

I OFTEN wonder why these beautiful little Orchids are not more grown, for when well established no particular difficulty will be found in their culture, and the plumes have just the quaint and singular structure and delicate tinting that appeals to lovers of Orchids. In habit they most resemble the *Pleurothallis* and *Masdevallias*, the blossoms occurring on short scapes from the apex of the stems. The plants grow naturally at considerable elevation in various parts of America, extending from Mexico southwards to Brazil.

They like cool moist conditions, a little warmer, if anything, than *Masdevallias*, especially in winter, but where no intermediate house exists they get along very well together. The roots thrive best in pots or baskets of medium size, these being well drained and only a thin surfacing of compost used. Three parts of sphagnum moss to one of peat fibre is suitable as a rooting medium, and the best time to repot or rebasket is just before the growth commences. If anything close or sour is about the roots remove this before placing the new compost about them, but disturb them otherwise as little as possible. Water freely all the year round, but especially during the growing season. *R. striata* (fig. 97) is of scarcely less interest, and the illustration will convey an idea of the general floral structure of the genus.

Like *Masdevallias*, these Orchids are apt to be attacked by thrips, and if allowed to make headway these troublesome insects soon ruin the appearance of the plants. Frequent spongings are necessary to rid them of these pests, or in bad cases the vapourising fumigator must be used. About a score species are known to botanists, but not half of them are probably now in cultivation, and the two mentioned below are those most generally grown.

R. antennifera is the type species, and is so called on account of the fine narrow pointed upper sepal and petals, which are supposed to resemble the antennæ of an insect. These and the other segments are yellow closely covered with purple spots. This species was found by Humboldt very early in the present century growing on tree trunks in New Grenada, while the beautiful *R. elegans* was found in similar positions in Caracas by Dr. Kaarten. It is not so large growing as the last named, but even more beautiful, the colours being charmingly graduated on the sepals and petals, which are white at the base, streaked and spotted with purple, and extending to deep golden yellow tails. It was introduced by M. Linden.—H. R. R.

STRAWBERRY BEDS.

CENTRES of attraction these either are or soon will be in thousands of gardens, and a few notes relevant to the plants and crops will at least not be unseasonable. The plants now in bearing demand attention in assisting the fruit to ripen by affording the clusters full exposure to the beneficial influence of light, and a free circulation of air round the plants. If strong weeds have grown rankly they not only shade the fruits, but abstract food and moisture from the soil, both of which are required in large measure by the Strawberries. Neither should the fruits be densely shaded with large luxuriant leaves, the abundant rainfall having tended to increase the leaf surface recently. Some of the oldest and inferior leaves might with advantage be removed, but avoid stripping away too freely large and perfectly formed leaves. The chief benefit accruing is the freer circulation of air.

The ripening fruit must have a clean bed of material, such as straw, to rest upon. Perfectly sweet clean straw is essential when used at a late period, but litter from the stables, if applied early

enough, is usually preferred. It becomes clean and sweet on the surface by washing with rain before the fruit is ripe. Supporting the trusses of fruit with forked sticks, or laying squares of glass, slate, or tiles underneath them, may also be employed. Short grass or anything that will troublesomely adhere to the fruit ought to be avoided. Immediately the fruit is ripe protection must be afforded from birds by placing nets over the beds, arranging some temporary framework for supporting them well above the fruit, and so that they can be readily removed to gather the berries.

The best period for feeding Strawberry plants is after the fruit is set and before it begins colouring. It is then in an active state of development, and the demands on the energies of the plants great. Soluble food, such as liquid manure and soot water, may be applied,

FIG. 97.—RESTREPIA STRIATA.

pouring it round the roots, where it can easily reach the masses of fibres, and be almost directly absorbed. In seasons when the soil is moist from frequent rainfalls, liquid nourishment may still be given with advantage. In very dry periods it ought to follow only upon copious applications of clear water.

LAYERING.—In addition to the fruit of the present crop we have to think about plants for the future. In order to secure well-rooted plants for establishing early, and affording fine fruits next year, the stronger of the first runners must be preserved on vigorous fruiting plants, removing the weaker at an early stage. When signs of roots are apparent on the most forward of the plantlets, these may be secured, each with a hooked peg or a stone, on the surface of small pots filled firmly with good substantial soil. Partly embed the pots in the ground, and supply water freely in dry weather. Cut off the runner wires extending beyond the pots, and when these are well occupied with roots the young plants may be detached, standing them in a shaded place for a few days, and they will soon be ready for planting.—E. D. S.

AURICULAS—ANCIENT AND MODERN.

As my earliest floral associations are connected with the Auricula, I have, of course, from time to time noticed any developments in its culture, especially in these later days, when so much attention is being given to a class of flowers which in my earlier days were hardly thought of. I mean the Alpine section, and what are now called Fancy Auriculas. Sharing, perhaps, the prejudices of the older florists, these classes have never "captured" me. The Alpines, no doubt, are very handsome, and of late years have been wonderfully improved; they are, moreover, much more easy to cultivate than the edge varieties, and increase more rapidly; they also seed very freely, so much so that one of the best Auricula growers I ever knew would not have one of them in his garden for fear of contaminating the seed of his choicer kinds.

With regard to what are called the Fancy varieties, they were evidently those which were known to the old Dutch florists, and appear in the flower paintings of many of the Dutch school. I imagine that the edge varieties are purely of English origin. The oldest list that I have seen contained only English names, and of those now in cultivation the oldest goes back to the beginning of this century. I have had a list which was compiled about 150 years ago, but it gives no indication as to what classes the flowers belonged, and not one of them appears to have survived to the present time. The jealousy with which the best varieties were watched by their owners, the care which was taken of them, treating them like spoiled children more than anything else, and the extraordinary composts in which they were directed to be grown, amuse those who in these days have adopted a more rational mode of proceeding.

That the Auricula will ever be popular, in the same sense and to the same extent in which the Rose and Carnation are popular, is, I think, very questionable; and warm and deep as is the love which the Auricula grower has for his favourites, he cannot be blind to the fact that all do not see with him. To many both the form and colour of the flower are stiff and formal, and my experience is that nine persons out of ten who come to see a collection of Auriculas will pitch upon the selfs in preference to the edged varieties, and the selfs are certainly the least highly developed of the four classes into which the Auricula is divided.

The north may certainly be regarded as more especially the home of the Auricula. It is amongst the weavers and cotton operatives of Lancashire that it had its strongest hold, and it was not until about twenty or twenty-five years ago that much attention was paid to it in the south. In the earlier part of the century it is true there were many keen and enthusiastic growers in and around London, but somehow or other they had nearly all either passed away, or abandoned the culture of the flower for something else; but the movement made to institute a southern branch of the National Auricula Society gave an impetus to the culture, while the offering of good prizes induced exhibitors to come forward; still the cultivators are comparatively few, although they have been very enthusiastic and successful.

As we are now arrived at the time in which it will be necessary without delay to repot our plants, in nothing will the alterations in culture be more manifest than in this operation. All the nastinesses of former days are discarded, and what the Auricula grower looks out for now is good strong turfy loam, such as is obtained in the Downs near Epsom and other similar localities. It is not clayey, and is full of fibrous roots, which, after it has been stacked for some time, decay, and afford admirable material for the purpose. Three parts of this, with one part of well-decayed cow manure, and one part of leaf mould, with some sharp sand, form a compost in which the plants flourish. There are some growers who will not treat all their varieties alike, but give to some more of one of the ingredients than to others; they will have their little heaps of the three kinds of soil used on their potting bench, and mix them according to what they think the plants require. I have never gone myself into such minute particulars, but have mixed all the compost I might require at once, and used it indiscriminately for all varieties.

Another point which has been more strictly insisted upon of late years is that of firm potting. It is true that some of the older florists did practise this. Amongst them was that keen and successful florist John Dickson of Acre Lane, Brixton, who was at one time the only trade cultivator in the neighbourhood of London, and who raised several varieties, which for a time maintained their position in our lists. They had, however, most of them too much body colour, and did not suit the more exact requirements of the present day. In potting them the soil should be carefully pressed down as close as is possible, and too large pots should not be used. Small pots are more desirable because the new roots sooner get to the sides, and the extension of growth is encouraged thereby. This would sound like heresy to the old Lancashire growers, whose "moogs" were 6 or 7 inches across, and proportionately deep, and therefore held a large quantity of material. After the plants have been repotted they

should be placed in a frame and kept rather close for a few days in a position in the garden facing north, so that they receive little sun during the summer months. Air should be gradually given to them, and growers are generally careful that they should not be exposed to summer rains, for the Auricula dreads wet more than cold, and much damp, especially *drip*, is fatal to the plants.

Although the new varieties which are added to our lists are few in number, especially when compared with those of other flowers, yet it is abundantly evident that those which are added put the older ones into the background. There was a time when Colonel Taylor, Page's Champion, and Lord Palmerston used to be found amongst our green edges, but I suppose Page's Champion is now represented by a very few plants, and its delicate constitution probably determines its complete extinction, and such varieties as Rev. F. D. Horner, Abbé Liszt, and Mrs. Henwood, with their better constitution and greater freedom in producing offsets, have quietly pushed the others into the background. So it is with the grey edges. Waterhouse's Conqueror, Oliver's Lovely Ann, and Smith's Bolivar have long since given way to George Lightbody (that best of all Auriculas), Richard Headly, Woodhead's George Rudd, and other flowers of equally sterling character. In white edges Reed's Acme, Woodhead's Mrs. Dodwell, and John Simonite, when it can be grown, have supplanted many of the older varieties; even Heep's Smiling Beauty, that very pretty white edge, has given way before the new comers. And so with regard to selfs. The advent of Heroine, Mrs. Potts, and Black Bess has completely changed the character of our exhibition stands, such varieties as Falkner's Hannibal, Martin's Mrs. Sturrock, and Campbell's Pizarro are now not often seen.

I have touched upon this subject because now is about the best time to increase one's stock; if put off till later it will probably be found that the varieties you wish for are not to be had; besides, it is well to get them under your own care during the summer months, and so, as I have said, good common sense, and the rejection of all quackeries, and of the pretence of superior knowledge, will recommend the flower to many who have hitherto abstained from its cultivation. The National Auricula Society stands in much need of new subscribers, and lovers of the flower who may wish to encourage it have only to send their names to Mr. T. E. Henwood, Auricula Villa, Hamilton Road, Reading, who will be happy to receive them.—D., Deal.

A BRITON IN BELGIUM.

(Concluded from page 460.)

I WAS a little staggered to hear that British Potatoes are not thought much of in Belgium, but my feelings were not so severely lacerated as to debar me from doing full justice to the small yellow Flemish Potato known as Jaune de Flandre, which is by no means a sort bursting with flouriness, but has delicious flavour. The fact is—and it is a very easy one to grasp—the British Potatoes sent to the Continent are the coarse market kidneys, not the high flavoured rounds like Sutton's Windsor Castle and Daniel's Universal, or the more delicate kidneys and pebbles, like Webber's Beauty, Duke of York, and Veitch's Syon House. The foreigners, together with some "Experimentalists" at home, are entirely unaware of the fact that we have a considerable number of sorts of splendid table quality, which are not grown in immense quantities for market, but are perfectly familiar to practical cultivators on a smaller and private scale. When the correspondent who has recently been adorning the pages of the Journal with opinions about Potatoes which he does not appear to have grown takes the trouble to acquire some knowledge of the best modern garden sorts, he will probably come to the same opinion as I have done—namely, that there are excellent eating Potatoes in as well as out of England. The Yellow Flanders is grown on an enormous scale in Belgium. Whether it can hold its own here against a large number of our best sorts, a few months will show me.

What is the best potash fertiliser? This is a question of great interest and no small importance. It has cropped up recently in the discussion on Potatoes. It will crop up again. The chance that threw me into the hands of Mr. Chas. Van Geert at Antwerp was in every respect a fortunate one, for this cultured and hospitable Belgian was able to combine the interest of a very fine tree and shrub nursery with the results of many years' experimental work in plant feeding. He has an opinion of his own about manuring, and he expresses it with a conviction far more impressive than the opinions of arm-chair theorists. The theory and practice of Mr. Van Geert is to rely upon stable manure for mechanical and nitrogenous action, but not for phosphates and potash, which must be applied as supplements. So far, perhaps, there is nothing particularly noteworthy, but when we find out the special fertilisers chosen and the manner in which the manuring is done, we learn something not without significance. The phosphatic manure used is bone powder, the potash one is the much-

abused muriate. The stable manure is spread out and the two artificials sprinkled on it, then the whole mixed together thoroughly. Sometimes the manure is applied in autumn, sometimes in winter, sometimes in spring, according as the quarters are cleared. Winter is preferable, but not always practicable in a nursery, or for the matter of that in a garden either.

What has particularly struck the Belgian nurseryman in connection with muriate (there called chlorure) of potash, is the fruitful habit it engenders. You may get more exuberance of growth with very heavy dressings of farmyard stuff or repeated supplies of nitrates, but you cannot get so much fruit. He instanced the fruiting of Conifers, such as *Abies concolor*, which has been much more abundant since the muriate was used than it ever was before. There is something practical here, surely. Remember that what is said is not the story of a trial in three flower pots of thumb size, with an observer armed with a powerful microscope at each pot, but it is the record of practical work on many acres of ground over a series of years. Therein lies its value. I recently ventured to say a word in favour of muriate of potash. At the time I wrote I did not even know Mr. Chas. Van Geert. Hence his spontaneous and emphatic testimony to the value of a much-maligned fertiliser came as a pleasant surprise.

Calmpthout, where the Van Geert nurseries lie, is a much-scattered village, about eight miles in extent, fifteen to twenty miles from Antwerp. It was a relief to find the nursery gate at the station part of the radius, my bicycle being at home. Calmpthout alluringly displays two inns at opposite corners on one side of the line, and the nursery entrance at the other. To a bicyclist there might be a moment of temptation; to a horticulturist there is none. He sees a line of Copper Beeches, an avenue of Conifers in scores of species, and is at once at home. The Copper Beeches are handsome pyramids, 12 to 15 feet high, and perfectly symmetrical. Some of them go to Great Britain, but we have not too many yet, nor have we of a numerous array of other beautiful shrubs, trees, and Conifers, many of which are either not known or very little grown by us.

There is an army of Acers, prominent amongst them being *campestre albo-punctatum*, *platanoides Reitenbachii*, *p. Schwedleri*, *Pseudo-platanus Leopoldi*, *P.-p. Prinz Handjery*, *P.-p. Woorlei*, and *virginianum aureum*, all beautiful forms. It would be too severe a tax on the memory to enumerate every noteworthy deciduous tree and shrub, but those who see them will not forget *Aesculus Briatti*, *Alnus glutinosa imperialis*, *Aralia Maximoviczi*, *Betula alba atro-purpurea* and *urticifolia*, *Caragana pendula*, *Castanea americana rubra*, the beautiful and hardy *Catalpa syringæfolia aurea*, *Cerasus Avium fl.-pl.*, and *C. sinensis pendula flore roseo*, *Cornus sanguinea aurea marginata*, *Corylus Avellana aurea*, *Cratægus Carrieri*, single white, with very large red fruits, *Fagus sylvatica purpurea* and *s. p. pendula*, *Fraxinus excelsior aucubæfolia*, *Liriodendron Tulipifera fastigiatum*, *Malus floribunda*, *Parrotia persica*, *Prunus Padus aucubæfolia* and *P. Pissardi*, *Quercus americana rubra* and *Q. pedunculata fastigiata*, *Robinia Pseudo-Acacia semperflorens*, *Sambucus canadensis filicifolia*, *Sorbus Aria lutescens*, *Tilia Beaumonti pendula*, and *Alnus americana pendula*.

Having regained breath the visitor will consign to memory a few shrubs proper, such as *Amygdalopsis Lindleyi*, *Ceanothus Gloire de Versailles*, *Hypericum Moserianum*, *Ribes pumilum aureum*, *Spiræa (Exochorda) grandiflora*, *Staphylea colchica*; several Lilacs, such as *Syringa vulgaris alba grandiflora Marie Legrave* and *Souvenir de L. Späth*, also *Viburnum plicatum*. Then he will gird himself for the Conifers, and in some reserve corner of his capacious brain he will stow away *Abies concolor*, *Nordmanniana*, *Veitchii*, *Alcockiana*, *Menziesii*, and *Hookeriana*; *Cupressus Lawsoniana Alumii*, *aurea, erecta, glauca*, and *intertexta*; *Juniperus tamariscifolia* and *virginiana aurea elegantissima*, *Larix Kæmpferi* and *leptolepis*; *Podocarpus Korayana*; *Retinospora filifera*, *pisifera aurea* and *plumosa aurea*; *Taxus baccata hibernica* and *aurea marginata*; *Thuja Lobbi albo-maculata*, *T. occidentalis Frœbeli*, *globosa*, *Hoveyi*, and *Späthii*, the latter most singularly distinct; and *Thuiopsis dolabrata*.

Being now in good training he will recall a few notable evergreens, like *Cotoneaster Hookeri*, *Phillyrea decora*, and *Skimmia obolata Veitchii*. But the number, if not the quality, being small, he will include with them a number of what the Belgians call heath soil plants, such as *Andromeda*, *Clerodendron dichotoma*, *Daphne Cneorum*, *Empetrum nigrum*, *Kalmia latifolia splendens*, *Ledums*, *Limonia trifoliata*, *Oxycoccus macrocarpus*, and *Xanthoceras sorbifolia*. He will include, too, some of the beautiful Honeysuckles the continentals grow, such as *Caprifolium bractypodum*, *C. flavum*, *C. japonicum*, and *C. sempervirens fuchsoides*; as well as *Glycine sinensis*; *Rubus fruticosus laciniatus*; huge quantities of *pontica* and *mollis* Azaleas, hardy Heaths, *Aquifoliums*, hardy Magnolias, and *Rhododendrons*.

These are but a few of the many good things at Calmpthout, but if anyone thinks he can remember more let him go and try. If he inquires, as I did, the object of the small boxes mounted on tall poles which are scattered over the nursery, he will learn that they are to harbour starlings, which are thought so valuable, on account of the grubs they destroy, as to be worth the expense of special shelters. There are 125 of these boxes, and still a few unfortunates are crowded out. In this sad experience they shared the fate of not a few horticulturists at Ghent during exhibition week. A free box at the end of a pole would have relieved some of the latter of an embarrassing task. But that is another story, and may not be told.—W. PEA.

NEW ZEALAND CHRYSANTHEMUM SHOWS.

MR. M. McDERMOTT, Honorary Secretary of the Cambridge Chrysanthemum Society, informs us that the show held at the end of April was larger than ever, and competition keener, more exhibitors taking part and the finances good. He further observes that "Mum" matters are booming, and much greater things are expected in the future.

The "Waikato Argus," in referring to the show, says the blooms were, on the whole, above the usual standard, and in some cases they were far in advance of it. We doubt if there has ever been such a stand of six Japanese exhibited at Cambridge in former years as those with which Mr. Wells took the first prize. With the exception of one bloom, *Rose Wynne*, they were all perfection. Amongst the new blooms of note that caught our attention were the following, exhibited by Mr. Wells:—*Modesta*, a brilliant deep yellow, probably about the best yellow Jap in existence; *White Swan*, a pure white of the hirsute section, large enough for a show bloom, and in every respect the superior of *Mrs. Alpheus Hardy*; *Marshall Oyama*, a pure white Japanese incurved, a splendid keeper; *Mons. Chenon de Lèche*, salmon buff; *C. H. Payne*, large amaranth, with bronze reverse; and *Australie*, a large Japanese incurved crimson lake, with silver reverse. In Mr. Buckland's stand we noticed *Emily Silsbury*, a large and handsome white; *J. H. Upton*, a very handsome full yellow, an Australian seedling of great merit; *Nyanza*, a large bloom of deep crimson colour; *Edith Tabor*, a rich clear yellow Jap; *Mons. J. Allernand*, large bloom, quilled after the style of *L. B. Bird*. Mr. McDermott had new blooms; *Stanley*, a good Jap, apricot bronze; *Glory of Pacific*, a light pink Jap; *Mrs. E. G. Whittle*, white, veined pink; *Olive Oclea*, Jap incurved, rich buff, shaded bronze; *Lewis Severs*, yellow and rosy purple, large Jap incurved. Of the true incurved section the new ones we noticed were *Mrs. R. C. Kingston*, pale pink; *Major Bonaffon*, rich golden yellow; *Major W. A. Day*, bright rose (a Christchurch seedling); *Mr. J. Kearns*, pure white, and *Bonnie Dundee*, bronze yellow.

The show was opened by the Mayor, who paid a great compliment to the President, Mr. Wells, for his successful efforts for promoting an extension of Chrysanthemum culture in the colony. Is he a connection of the "Earlwood Wells," who introduces antipodean Chrysanthemums? Shows have also been held at Essendon, Oakleigh, and Brighton, "down under."

MISS NELLIE POCKETT.

Mr. Thos. Pockett, a successful Australian raiser of Chrysanthemums, writes: "Miss Nellie Pockett has taken the champion position at three shows held in Victoria, and is now a general favourite. Early buds give immense blooms of great depth and pearly whiteness. It is easier to grow than *Madame Carnot*, of which it has become a dangerous rival." It is distributed with others by Mr. Wells of Earlwood. Mr. Pockett also refers with approval to a new incurved variety, *Tooronga*, for which he has obtained a first class certificate; a very dwarf grower, with rather more colour than *Globe d'Or*. We have in hand interesting notes from Mr. Pockett on the raising of seedling Chrysanthemums.

HULL AND EAST RIDING CHRYSANTHEMUM SOCIETY.

WE have received the schedule of this continuously prosperous Society. The prizes are good as usual, and it is particularly encouraging to observe the silver challenge and cups offered by amateurs—the 25-guinea vase, by William Wheatley, Esq.; silver cups, by the Mayor (J. Crook, Esq.) and Sheriff (Henry Whittick, Esq.). A. S. Ayre, Esq., provides a challenge plate, value 10 guineas, in the ladies' decorative class; and the tradesmen of Hull a piece of challenge plate for blooms grown by amateurs. The Society's chief difficulty appears to be in obtaining a building large enough—large as the space is in the Artillery Barracks—for the accommodation of visitors. Last year a bold experiment was made in doubling the price for admission during the evening of the second day of the show. While it is gratifying to know that no pecuniary loss resulted, it is all the same a pity that space cannot be found for thousands more of the inhabitants of Hull to enjoy the fine and variedly attractive exhibitions.

KINGSTON CHRYSANTHEMUM SOCIETY.

WILL you please permit me to mention that in response to my recent reference to the financial position of this Society, Mr. W. Wells of Earlswood has kindly sent me towards the fund the sum of 20s. Mr. Wells does not beat about the bush in doing so, or assume any airs of special generosity. He says, in a business-like matter of fact way, "I recognise the great value to the trade of Chrysanthemum exhibitions, and should feel it to be a grave misfortune that an old and eminent society like that at Kingston should go under from lack of proper support." That is good sense. Besides the trade, there are in the kingdom very many private growers of Chrysanthemums who have largely benefited by the Kingston Shows. I shall be delighted to be the recipient of any of their practical sympathy, *a la* Wells, also of promises from anyone of really beautiful honorary exhibits, especially of a decorative nature.

No doubt all shows suffer more or less through stereotyping. There is such a tendency, because it is so easy to go on reproducing the classes without variation every year. One of the great charms of the Shrewsbury Show is the constant introduction of varied and model classes. The National Chrysanthemum Society has also benefited in the same way. Mr. Wells suggests the arrangement at Kingston of an honorary or badge class for trade novelties in Chrysanthemums, such as twelve varieties in pairs, there being no such class, so far as he knows, in existence. I should like it to be a class for treble blooms, in twelve varieties, set up in vases, varieties to have been put into commerce during the present year, or not yet in commerce.—ALEX. DEAN.

P.S.—Since writing the foregoing I have received another 20s. from an "Old Judge," who describes the Kingston shows as historical, and in past years did enormous service in widening the interest in Chrysanthemums in this country. The group classes originated at Kingston, and it was the first society to give generous prizes for Japanese blooms.—A. D.

WEATHER IN LONDON.—Summer seems to have come at last. Gardens are gay with hardy flowers, and haymaking is in progress in the surrounding counties.

— LITTLE REMINDERS.—During the press of work at the busy season certain small matters are apt to be overlooked; but, if small, they may be important. The success of certain processes depends on their being carried out in good time. It is so with the items in routine to be noticed. Let the work be done at once and benefit will be certain; defer it for a month or more and little good will accrue. Here follows my little trio:—

— RASPBERRIES.—Where the suckers that are to form the canes for future fruiting are thickly placed, good will be effected if the weaker and less promising are removed, retaining sufficient of the more promising without overcrowding, and keep the spaces between the rows clear of weeds.

— GOOSEBERRIES.—Single, double, and multiple cordons on walls and fences require their summer growths shortening. This operation may now be commenced, reducing all the foreright shoots to two pairs of leaves, allowing the leading shoot on each cordon branch to extend unchecked.

— RED AND WHITE CURRANTS.—The summer pruning of these I find of great value. They require identical treatment. Whether grown as cordons or bushes in the open the side shoots must be freely shortened back, leaving two pairs of leaves. Summer reduction of growth is highly beneficial. It frequently clears the trees of severe attacks of aphids, which infest the points of shoots, and allows a freer circulation of air around the lower leaves as well as the fruit clusters.—A WORKER.

— INTERNATIONAL KIDNEY POTATO.—This once famous variety is now to be seen in every grocers' and fruiterers' window, grown evidently at Malta or in the Channel Islands. Very few persons, perhaps, recognise it, but that is the variety which can be purchased cheaply in a young state. International has had the merit of being the best abused Potato ever put into commerce. It is odd that it should now be so universally grown and consumed as it is. Such are the vagaries of destiny. The Canary Islands Potatoes, which are smaller and earlier, the skins being quite hard set when they reach us, are evidently of Snowflake and Snowdrop, or closely like these well known varieties. I have planted greened tubers with other varieties to see what they really are, and though later than those from home-saved seed, are now pushing freely through the ground.—A. D.

— ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting will be held on Tuesday, June 28th, in the Drill Hall, James Street, Westminster, 1-5 P.M. The Rose Show, which was to have been held on this date, is now postponed until July 12th, and all intending exhibitors are desired note this change. At three o'clock a lecture will be given by the Rev. Prof. G. Henslow, V.M.H., on "Some of the Plants Exhibited."

— GARDENING APPOINTMENTS.—Mr. J. Snell, for five years foreman with Mr. H. J. Clayton, Grimston Park, Tadcaster, has been appointed head gardener to J. Hawthorn Kitson, Esq., Elmet Hall, Leeds. He succeeds Mr. T. Bonsall, who died very suddenly on Tuesday, 7th inst., when in Leeds on business. Mr. J. Creed, late foreman at Middleton Park, Oxon, has succeeded Mr. Rogers as gardener to J. D. Sanders, Esq., North Sandsfield, Gainsborough, Lincolnshire. Mr. W. Wingfield, late foreman at Hindlip Gardens, Worcester, has been appointed gardener to Sir Henry Delves Broughton, Bart., Doddington Park, Nantwich.

— THE NEWCASTLE-UPON-TYNE FLOWER SHOW.—As already announced, this show will be held in conjunction with the Northumberland Agricultural Show in the Recreation Ground on Wednesday, Thursday, and Friday, 13th, 14th, and 15th July. We are officially informed that this will be the largest show ever held in the North of England. A deputation from the Council of the Royal Horticultural Society will travel from London to visit the show and make awards. Several prominent nurserymen from different parts of England have made application for space. The whole show promises to be a great success.

— HORTICULTURAL CLUB.—The last monthly dinner and conversazione for the season took place on Tuesday, June 14th. As usual at this time the attendance was not as numerous as it generally is. The Chairman of the Club, Sir J. D. T. Llewelyn, Bart., M.P., occupied the chair, and a very interesting lecture was given by Mr. C. T. Dreury, V.M.H., on "Fern Variation in Nature and Culture." The lecture was illustrated by some remarkably beautiful illustrations of Nature-printed Ferns, by the late Col. Jones; it gave rise to an animated discussion, and a cordial vote of thanks was accorded to the lecturer. The annual excursion of the Club was fixed for July 19th, of which members will receive full particulars in due course.

— MAGGOTS ON FRUIT TREES.—Your correspondent, on page 481, seems to have suffered the same as myself with these disastrous enemies. During the last two years I have planted at least 200 young Apple trees, and throughout the month of May I was at my wit's end to know how to rid them of the hundreds of these maggots. Having so much work on hand, I was only able to spare a man two days a week hand-picking them. Seeing that this would not keep them down I was determined to try another plan, which I am glad to say has produced a gratifying effect. I had previously used the XL All mildew wash for green fly, red spider, thrips, and mealy bug, as well as mildew, with good results, and resolved to try it for this pest, which had become very disastrous. What they are I do not know, but this preparation is sudden death to all that get hold of it. As a preventive another year I intend to syringe every tree (Apples and Apricots especially) with quassia water, about the month of March, with softsoap added. I have an idea this will keep the parents off, and thus compel them to lay their eggs elsewhere. I shall anxiously await the opinion of Mr. Abbey, who seems to have made a successful study of gardeners' enemies.—G. BURROWS, *Berwick, Shrewsbury*.

— THE CUCKOO AND CATERPILLARS.—Mr. W. C. Stone inquires, on page 480, if other gardeners have had a similar experience to that he relates respecting the cuckoo. For several years I have found the bird an undoubted friend in the garden, clearing the Gooseberry plantation of the caterpillars, and very rarely do the bushes here become defoliated to any extent from their ravages. I have, however, not found the bird so bold as your correspondent; his visits being made in the early morning or evening. It is singular how early in the season the bird finds its prey. On examining the bushes for the pest, I have noted only a stray caterpillar here and there, but these disappear very quickly once the cuckoo is on the warpath. There is, as Mr. Stone points out, a great saving of labour at a time when this can ill be spared to deal with the pest by hand. The cuckoo, therefore, deserves well of the gardening fraternity, as well as the forester, in carrying on such a useful work in its search for food. There are other birds which are useful in some seasons of the year, but their value is more than counterbalanced by the harm done at other times. This cannot be said of the cuckoo, and I am glad to find there are others who can furnish an appreciative testimony for the bird, apart from its welcome notes in the spring.—W. S., *Rood Ashton*.

— FROST IN LINCOLNSHIRE.—A correspondent writing from North Lincolnshire on the 17th inst. described the weather as very cold then, and stated that a sharp frost on the previous night had "scorched" all the Potatoes in low lying situations. Kidney Beans have also been destroyed. This savours somewhat of winter five days off midsummer.

— DAMAGE DONE BY HAIL IN SEVEN MINUTES.—A year ago, it will be remembered, a seven-minutes storm of hail swept over Essex. The relief fund started for the agriculturists whose property was damaged has now been finally distributed, and the accounts published in detail. They show what terrific destruction such a visitation can inflict in so brief a space. It has taken £45,147 to relieve the worst cases, and a great deal of general damage remains uncompensated. The number of relief cases dealt with by the fund was 3188. The compensated damage alone, therefore, amounts to nearly £7000 per minute for the duration of the storm.

— TREE CARNATION COUNTESS FERRERS.—There is a fine collection of the best Carnations at St. Anne's, Clontarf, Dublin. Among these one of the finest is one raised there, and named Countess Ferrers. It is a favourite with Lady Ardilaun; and Mr. Campbell, the gardener, speaks highly in praise of the flower. Although all its qualities could not be tested—the size of its flowers, the beauty of their colour, and the fragrance they exhaled showed it to be a desirable variety. The flowers are large, well formed, and are of a beautiful blush colour, with a powerful but not oppressive Clove scent. It is also a good grower and a perpetual bloomer, besides having the property of opening well in water, and lasting for three weeks when cut.—S. A.

— PHENOLOGICAL OBSERVATIONS.—We have received a report on the phenological observations for 1897, by Mr. Edward Mawley, F.R.H.S. It is issued in the form of a manual of twenty-five pages closely packed with matter, including carefully tabulated records and diagrammatic illustrations. It bears the impress of admirable diligence and care, and will be appreciated by those who take particular interest in the weather and its influences on vegetation. Mr. Mawley sums up by saying:—"There was nothing very exceptional about the weather of the past phenological year, as regards its effects on vegetation, beyond the heavy rains in March and the three dry periods of May, July, and October. Until about the middle of May wild plants came into blossom in advance of their usual time, but throughout the rest of the flowering season they were more or less behind their mean dates in coming into bloom. Unlike the previous year the crop of wild fruits was very poor, with the exception of Blackberries and Nuts, which were unusually plentiful. There were also fair crops of roots and Potatoes. Apples, Pears, and Plums, and especially the latter, yielded badly, while the small fruits were about average." The report is taken from the "Quarterly Journal of the Royal Meteorological Society," vol. xxiv., No. 106, April, 1898.

— LILY DISEASE.—The cultivation of the Lily as an ornamental plant is rapidly extending in this country, and it must be admitted that many of them well repay the care and attention bestowed upon them. Whether grown indoors, however, or out in the open, these Lilies are liable to maladies which often perplex cultivators. A common ailment is characterised by the spotting and distortion of the leaves and flowers, and usually the stunting of the plant. In Bermuda and in the United States this disorder, known as the Bermuda Lily disease, frequently destroys from 20 to 60 per cent. of the crop. Amongst the causes of the malady are included worn-out soil, premature cutting of flowers, too early harvesting of the bulbs, carelessness in the selection of stock for propagating, bad treatment during forcing, and the ravages of insects. Investigations carried out on behalf of the United States Department of Agriculture indicate the disease to be due to a combination of these causes. Bulbs become weakened through improper selection and propagation, and this weakening is aggravated by attacks of mites and of certain fungi and bacteria. During forcing the bulbs may become weakened by over-watering, or by allowing the roots to get too dry, and then using an excess of water; in such cases the leaves become badly diseased. The blotching and distortion of the foliage are often due to the direct attack of several species of aphides and of young mites, or to the injection of water into the leaves by syringing. To check the disease proper cultivation, selection, and propagation are recommended, in order to improve the stock; suitable rotations will prevent the increase of mites and parasitic fungi. The stems should be left on the bulbs to secure proper ripening, and care should be exercised in planting, all injured bulbs being discarded. As far as practicable, injurious insects should be kept in check from the start, and continuous care should be bestowed upon watering and ventilating. Chemical fertilisers are recommended in preference to farmyard or natural manures.—("Times.")

— A POTATO BOYCOTT IN SCOTLAND.—The "North British Agriculturist" says, "The attempted boycott in the Potato trade is proving a miserable fiasco. With the few remaining stocks of old Potatoes selling up to £6 10s. per ton, and new Potatoes in keen demand at prices ranging from £30 to £45 per acre, the early Potato growers can well afford to snap their fingers at the boycotters. Several of the more extensive and better-class dealers, particularly the Messrs. Paton, are so disgusted with the boycotting business that they are threatening to clear out of it. The boycotters may not see it themselves, but they are doing their best to make themselves the laughing stock of the country."

— WISTARIA MULTIJUGA.—A good-sized bush of this rather rare species is to be seen in flower near the Pagoda at Kew. Although not so useful for general purposes as *W. chinensis* it is well worthy of cultivation. It is a Chinese species, and is chiefly remarkable for the length of its pendulous racemes. It grows freely, and may be had either as a climber or bush. The flowers are similar in colour to those of *W. chinensis*, and are borne in loose racemes 2 to 2½ feet in length. The leaves are about 15 inches long, and made up of about fifteen leaflets; each of those on the larger leaves being 3 to 4 inches long by 1½ inch wide. It can be grown quite as readily as the common *Wistaria*, and is worth remembering by those who are seeking variety among hardy climbing or sub-climbing shrubs.—D. K.

— SPRING TRENCHING AND ITS RESULTS.—I was somewhat amused on taking up the Journal to find that "Spring Trenching and its Results" still remains an unsettled question. As no doubt each gardener will continue the practice that he has found satisfactory, it seems useless prolonging the discussion. My method of treating strong soil over a period of nine or ten years has so far proved successful that I shall certainly need to be very much more "philosophised" before leaving all my ground undug through the winter, especially should there be a spell of dry weather in the autumn, as was the case in 1897. I take it that the recommendations as to digging and trenching heavy soils were not confined to any particular district, but advanced for universal adoption, hence my note of inquiry. No one respects Mr. D. Thomson's talents as a gardener more than myself, but it is possible, even for the best of men, to be too exacting on questions and methods which are open to such variable influences as weather changes in our own erratic climate.—F. DUNN.

— A WONDERFUL BUNCH OF GRAPES.—Under this heading we read in an evening paper:—"The following curious circumstance may be given credence to (says a 'Standard' telegram from Paris), as it is reported by the 'Temps,' a serious paper. There is growing in the garden of a M. Patapy of Condon, in the Gers, a bunch of Grapes, which, though but partly developed, already measures a little over 16 inches in length. It is put forth by a young shoot, grafted on an American plant, which had not till then given any fruit." The *Journal of Horticulture* is a "serious paper," and does not regard such a bunch of Grapes as either "curious" or "wonderful." It has registered as "curious" a bunch of Grapes pushing out of the thick hard stem of a Vine under a stage near hot-water pipes, and no leaves within 4 feet of it; and as "wonderful," for size a bunch which measured 27 inches in length and the same in breadth across the shoulders, with a circumference, measuring around the contour of these, of 96 inches. That is the record for "size." For "weight" (another bunch) it is 26 lbs. 4 ozs. These examples were produced in Scotland.

— ROYAL METEOROLOGICAL SOCIETY.—At the last monthly meeting of this Society at the rooms of the Royal Astronomical Society, Burlington House, Mr. F. C. Bayard, L.L.M., President, in the chair, a paper by Mr. R. C. Mossman, F.R.S.E., was read on the "Frequency of Non-Instrumental Meteorological Phenomena in London with Different Winds from 1763-1897." In previous papers the author has discussed the secular and seasonal variation of various phenomena, and he now gives the results of an analysis of the direction of the surface winds observed during the occurrence of snow, hail, gales, thunderstorms, lightning, fog, and aurora. Snow is of most frequent occurrence with north and east winds, and least common with S.W. winds. Hail showers occur most often with W., N.W., and N. winds. Gales are most frequent with W. and S. winds. The greatest number of both summer and winter thunderstorms occurs with W. winds, although the values in summer are high with E., S.E., and S. winds. The greatest number of fogs are recorded on calm days closely followed by days on which the wind blew from the east. A paper by Mr. A. L. Rotch was also read on "The Exploration of the Free Air by Means of Kites at Blue Hill Observatory, Mass., U.S.A.," and their employment was strongly advocated as of prime importance for the advancement of meteorological knowledge.

ROSE SHOW FIXTURES IN 1898.

- June 23rd (Thursday).—Bath (N.R.S.) and Ryde.
 „ 25th (Saturday).—Windsor.
 „ 28th (Tuesday).—Leeds,* Southampton,† Sutton, and Isle of Wight (Carisbrook).
 „ 29th (Wednesday).—Brockham, Canterbury, Croydon, and Richmond (Surrey).
 „ 30th (Thursday).—Gloucester, and Norwich.
 July 2nd (Saturday).—Crystal Palace (N.R.S.).
 „ 5th (Tuesday).—Diss, Harrow, and Hereford.
 „ 6th (Wednesday).—Chelmsford, Ealing, Farningham, Hanley,† Hitchin, Redhill (Reigate), and Tunbridge Wells.
 „ 7th (Thursday).—Woodbridge.
 „ 8th (Friday).—Ulverston.
 „ 9th (Saturday).—Manchester.
 „ 12th (Tuesday).—Westminster (R.H.S.), and Wolverhampton.*
 „ 13th (Wednesday).—Bedford, Ipswich, Maidstone, and Newcastle-on-Tyne.*
 „ 14th (Thursday).—Halifax (N.R.S.), Brentwood, Canterbury (Hospital Fund), Helensburgh, Reading, and Eltham (altered from June 30th).
 „ 16th (Saturday).—New Brighton.
 „ 21st (Thursday).—Sidecup.
 „ 26th (Tuesday).—Tibshelf.
 „ 28th (Thursday).—Bedale.

* Shows lasting three days. † Shows lasting two days.

—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

NATIONAL ROSE SOCIETY AND TWO-DAYS SHOWS.

AS long as my excellent friend Mr. Biron was floundering in a muddy sea of his own creation I did not think it needful to notice his letter in the *Journal* of May 5th, for I had such confidence in his agility as an old cricketer that he would not be inconvenienced by his mistake; but when he drags others down who are perhaps not gifted with such powers as he has, I think it better to set the matter right. I can see how he has been misled. My excellent co-secretary, Mr. Mawley, gives as soon as practicable each year a list of the Rose show fixtures of the coming season, whether they are those of the affiliated or non-affiliated societies, and the error into which Mr. Biron has fallen is that of supposing that all the societies in that list were affiliated. The fact is that no society which is affiliated to the National holds more than one day-shows, and the Committee have more than once lately refused to entertain the notion of holding a provincial show which ran into two days.—D., *Deal*.

ROSA SPINOSISSIMA.

IN the Rose garden near the Pagoda at Kew a large group of this Rose and its varieties may be seen in flower. The type produces white flowers about 2 inches across. Among the varieties, however (double and single), a great range of colour exists, some being white, some cream, others pink, &c. Perhaps the best and most distinct of the varieties is that known as R. s. var. *altaica*, or R. *grandiflora* as it is sometimes erroneously called. At Kew this variety grows 6 feet in height and flowers very freely and early. The flowers are white, 3 inches in diameter, and are followed by dark purple fruits. For planting in groups in a semi-wild state, or for the front of a shrubbery, a selection of the varieties of this species will be found very useful. If planted in good soil to begin with they are little trouble afterwards.—D.

COLCHESTER SHOW.—JUNE 16TH.

WHY Colchester Rose Show should be so particularly early each year I have endeavoured, without much success, to learn from the courteous and painstaking Secretary, Mr. Orpen. All I can understand is that it must be a Thursday, and that Thursdays are much in request and limited in number. My imagination fills up the rest with the supposition that on some special date there is a scramble, or game, or contest of some sort for the best Thursdays—those “on the line,” so to speak—and that Colchester has hitherto come off second best, and—to use the same metaphor—been “skied.” There was some talk of putting it off a fortnight before the day; but on the appearance of warm weather it was resolved to stick to the original date, and after that it was simply a cruel fate that the four days before the show should be so dull and cold.

The show was held in the grounds of C. E. Egerton-Green, Esq., in the town, and the schedule was, as usual, a perfect model of that of a dutiful affiliated society of the N.R.S. Good Roses, as may be supposed, were very scarce—indeed, but for Mr. Mount's contribution, and the open class of twelve Teas, and some *Maréchal Niels*, they would have been almost absent.

For thirty-six, open, Mr. Mount was easily first; some of his blooms bore traces of not having quite opened of themselves; but one was only too glad to see a good Rose at all, to be hypercritical. His best blooms were all Teas—*Maréchal Niel*, *Souvenir de S. A. Prince*, *Catherine Mermet*,

and *Rubens*. Messrs. D. Prior & Son were second, having *Cleopatra*, *Souvenir de S. A. Prince* and *Niphetos* in good form; and Mr. B. R. Cant was third, having also Teas for his best flowers.

In twelve Teas, open, the judging was at first sight not so easy, the twelve of Mr. Prince of Oxford being very much the best, but having a terribly “gone” *Maréchal Niel* prominently displayed which spoilt the whole. However, pointing soon showed that even taking off one for this bloom it was far ahead, having *Souvenir d'un Ami* (medal in the open division), *Cleopatra*, *Princess of Wales*, and *Jean Ducher*, fine, clean, and good. Messrs. Frank Cant & Co. were second with neat and regular but smaller blooms, *Cleopatra*, *Catherine Mermet*, and *Maman Cochet* being the best among them. Messrs. Paul & Son of Cheshunt were third, with a pretty specimen of Dr. Grill in the box.

The garden Roses (open) were placed in the following order:—Messrs. F. Cant & Co., B. R. Cant, and Paul & Son, but it is difficult to judge these properly if no limit (provided there are three) is placed to the number of trusses in a bunch.

In the amateur classes, Mr. R. E. West of Reigate, the only exhibitor, was placed first for eighteen. Then followed three classes with no entries. In six Roses, H. Egerton-Green, Esq., was first, showing a fine bloom of *The Bride*. He was also first for twelve Roses, the Mayor's prize, having in this box a *Maréchal Niel*, given the medal for best Tea, which was good, and an *Alfred Colomb*, and awarded a similar honour for best H.P., which was poor. Mr. R. E. West was second, and Rev. J. H. Pemberton third.

Roses were too scarce for anyone to show trebles.

In six similar Teas, all showed *Maréchal Niel*, Mrs. Arthur Cant coming first, Rev. A. C. Johnson second, and Mr. H. Egerton-Green third. In six garden Roses the last-named gentleman was first, having a beautiful bunch of *Reine Marie Henriette*, one of the blooms being apparently as good as most of the red H.P.'s shown elsewhere.

The show of herbaceous flowers was very good, Mr. Burrell of Cambridge taking first prize in the open class, followed in the order named by Messrs. Notcutt and Jacobi of Ipswich. Among amateurs Mr. H. Egerton-Green was first, followed by Hon. W. Lowther and Mr. Orpen, with an extra prize for *Lady Du Cane* of Witham. Messrs. R. Wallace & Co., Colchester, showed a fine stand of *Iris*s, not for competition.

The dinner table decorations were keenly contested, Mrs. R. Wallace taking first prize in the first class. The Judges must, I think, have been influenced here by three or four lovely blooms of the new *Calochortus* (*Purdyi*), which gained a first-class certificate a short time before from the R.H.S. This delicate flower, with its wonderful coating of white hairs, is beautiful indeed. Miss Moore was second, and Mrs. Arthur Cant third.

The next dinner table class was for wild flowers only. Miss A. F. Harwood was first, with wild Roses; Miss M. Scott second, with *Iris*s and Reeds; and Mrs. R. Wallace third, with a most interesting though perhaps not effective scheme of bog plants—*Ragged Robin* and *Cotton Rush* as the tall plants, and *Drosera* and *Stagshorn Moss* for the low ones.

In a class for a vase of wild flowers, for girls under sixteen, there were no less than twenty exhibits; and almost all of these were arranged with a taste that was quite unknown twenty years ago, before the educating power of these competitions had done its work. In another class, for like exhibitors, where a certain space had to be covered with wild flowers, the first prize was given to *Honeysuckles*, second to *Broom*, *Sorrel*, and “*Bull's-eye*” *Daisies*, and the third to a simple arrangement (which I liked best of all—it was just a piece of meadow) of “*Bull's-eyes*,” *Buttercups*, and *Grasses* alone. The first and third prizes were, I understood, won by the daughters of a labourer.

The show of *Asparagus* is always a noted feature at Colchester. In the open class for 100 heads Messrs. W. Stroulger was first, R. T. Daniell second, and F. Chapman third. The last named was last year the winner of the challenge cup for three bundles of 100 head each, presented by Mr. G. Monro of Covent Garden; but this year it was easily won by Mr. W. Godfrey of Colchester.

A gleam of sun came out in the afternoon, and a capital attendance resulted. Some of us, as usual, went off to see the grounds of Messrs. F. Cant & Co. and Mr. B. R. Cant. Roses were backward, but promising. Standards undoubtedly looked the best everywhere. Here and there orange fungus sparkled, but no mildew was present. Many large leaves had holes driven through them by the hailstorm of a short time back, but it was nothing like the memorable storm which occurred on the day of the Rose show last year. I was sorry, but not surprised after what I had heard, to find the veteran, Mr. B. R. Cant, too ill to see me, and distressed to find his good wife in a very poor state of health. On the other hand, it was pleasant to find Mr. W. Prior pretty well and cheerful in the exhibition tent once more.—W. R. RAILLEM.

NEW PUBLIC PARK AT TIPTON.—The first prize of £25 in the public competition for the best plan for laying out the New Victoria Park at Tipton has been unanimously awarded to Messrs. William Barron and Son, Elvaston Nurseries, Borrowash. Their plan shows a lake about 3 acres in extent, cricket and recreation grounds, lawn tennis grounds, bowling green, band stand, and shelters. They also furnish plans of lodge, entrance gates, ornamental fencing, &c. The park is 33 acres in extent. The second prize was awarded to Mr. John Perry, architect, Tipton. There were ten competitors.

SILICO-FLUORIDE OF AMMONIUM.

YOU were good enough to allow me to draw attention, in the *Journal of Horticulture* for the 21st October last, to the advantages of silico-fluoride of ammonium as an insecticide and fungicide. Since that date I have received letters upon the subject from all parts of the world. The substance is extensively used in the United States of America, and appears to have attracted the attention of the Department of Agriculture some time ago, so that our transatlantic friends are ahead of us in this respect, as in some others.

The following method of making the substance is simple, and all the ingredients are perfectly harmless. Obtain 1 lb. of the strongest hydro-fluosilicic acid; it ought to fume in the air, but it does not attack glass bottles or corks. Dissolve this in a quart of rain water. Then dissolve a quarter of a pound of the strongest ammonia (liquor ammoniæ fortiss.; 880 is the trade name of it) in a quart of rain water. These ingredients will cost about 1s. per lb. and 6d. per lb. respectively. Mix the two fluids, and allow the excess of silica, which is always present in the acid, to settle down. The clear liquid will be a tolerably strong solution of the silico-fluoride which must be greatly diluted with rain water before applying to plants.

Microscopic investigation has shown that it attacks and destroys eelworms, towards which it behaves like a nitrifying micro-organism. This action is very probably due to the presence in the eelworm of some alkaline base for which the silico-fluoride has a strong affinity. I gave my address in my previous communication; cheques for £50,000 can always be sent there. See page 571, December 16th, 1897.—W. M.

[No doubt they can, and perhaps our correspondent, after reading the following observations and record of experiments with silico-fluorides, may think Mr. Abbey entitled to a share in the spoil.]

SILICO-FLUORIDES—THEIR ACTION ON CROPS AND PESTS.

IN order to understand the action of any substance, the nature of its components must be chemically defined, and in strict accordance with ascertained facts. For these we are beholden to the science which treats of the nature, laws of combination and mutual actions, of the minute particles of the different sorts of matter composing the earth, and the products of the compounds they form. Chemists have shown, by their investigations, that when the different substances found in the earth are submitted to various methods of treatment, the great majority of them can be broken up into others of a less complicated nature. By submitting all the rocks, minerals, animal and vegetable substances, to appropriate processes, what are called the chemical elements are obtained. These are expressed by symbols, each corresponding to the initial letter of its Latin name, or where several elements have the same initial, a small letter is attached to it for the sake of distinction. Thus C is the symbol of carbon, and Ca that of calcium. These symbols are always understood to represent, not an indefinite quantity, but an atom of each element. The symbols

of compounds are formed by the juxtaposition of those of their elements. Thus—HCl expresses the fact that this compound contains single atoms of its constituents, hydrochloric acid being a compound of one part of hydrogen (H, 1.00) and 35.37 of chlorine (Cl, 35.37). When more than one atom of an element exists in any compound this is indicated by a coefficient placed after its symbol. Thus H_2O = water is a compound of two atoms of hydrogen and one of oxygen.

I give the foregoing, as the charge is sometimes made of the terms being of no use to practical cultivators without an explanation of their meaning, and also for the purpose of inculcating the desirableness to gardeners of sound knowledge on the principles of chemistry as essential to successful practice, or the economical and profitable production of crops. Science is now, fortunately, the handmaid of horticulture, and the gardener finds his handbook of chemistry useful when its instructions

and principles are carried out in the field of active operations. I can appreciate the horror with which some hard-headed gardeners regard theoretical horticulture, which means with them all theory and no practice; but I cannot understand why the gardener, still relying on his hand and on experience, cannot see his way to add science to practice. Technical education has greatly changed, and instead of being based on mere book-learning it has become "Practice with Science." The best results are obtained where theory is illustrated in practice, and this brings us to the subject on those sound principles.

FLUORINE.

This element, F, atomic weight 19.00, is very widely distributed indeed, and mainly known in combination, chiefly as calcic fluoride (CaF_2), and commonly called fluor, fluor spar, or Derbyshire spar. This is composed of 51.3 of calcium or lime, and 48.7 of fluorine. It is the source of all the hydrofluoric acid used in the arts. The substance fluorine has been detected in blood, milk, and urine; in plants; in copro-

lites and other mineral phosphates; and forms an essential part of the bones and teeth of animals. We, therefore, have it in solid and liquid fertilisers, in bonemeal, ground phosphates, and in superphosphates. It means we use it as manure, and its action, so far as I can make out, is decisively anti-fungoid, for I find cereals strengthened in the straw by the use of powdered fluor spar acting on silica by the sulphuric acid present in the soil and disengaging hydrofluoric gas, which corrodes or decomposes the silica.

Anyone can try this by treating powdered fluor spar with sulphuric acid, and covering with sand or powdered glass. It will give an idea of how fluorine applied infinitesimally in manures and fertilisers acts on the silica of the soil, and thus supplies plants steadily with that element. Make no mistake in the matter, for fluorine does nothing by itself, the sulphuric acid being essential for the evolution of the hydrofluoric acid, and this, decomposed by potassium and sodium, gives the fluorides of potash and soda, which act promptly on eelworms and on fungi. I had an idea, long ago, that these substances would save Potatoes from the disease caused by *Phytophthora infestans*, but I did not then know that

FIG. 98.—CATTLEYA MENDELI OAKES AMES. (See page 515.)

this pest passed over in the "set," and was practically out of reach by any dressing applied to the land.

HYDROFLUORIC ACID.

It may be stated that this substance is prepared by decomposing fluor spar with sulphuric acid in a retort of lead, the acid distilling over being collected in a leaden, platinum, or gutta-percha bottle. It is a very powerfully corrosive substance, and very dangerous to have anything to do with, even in the aqueous solution, being then very destructive to animal and vegetable tissues, and its vapour irrespirable. In this state it reacts with silica to form silicic fluoride—a transparent colourless gas, decomposed by water. This will be enough to connect the substances known as fluorine (F) and hydrofluoric acid (HF) with the silico-fluoride noticed in the *Journal of Horticulture* by Mr. W. Mills, October 21st, 1897, page 391, and put forward by him as a germicide.

Fluor spar, or Derbyshire spar, so far as I know, has not been used as a general dressing for land, though beds of it at Alton Moor and Castleton, in England, and extensive veins in the United States, exist. The use of it, however, for the experimental purposes already foreshadowed were satisfactory, the rate of application in powder being 1 stone per rod, 1 ton per acre. The acid I have not used, but have found fluoride of potassium a powerful fungicide and insecticide at a strength of 1 part in 1000 parts of water, or 1 fluid ounce to $6\frac{1}{4}$ gallons, this being strong enough for the foliage of most plants, or as much as it will bear without injury. The roots will endure a greater strength, but plants vary greatly in their susceptibility or otherwise to injury.

SILICO-FLUORIDES.

Mr. Mills, on the page previously quoted, gave instructions for preparing silico-fluoride of ammonium, and in the page following a communication was also given by another authority on the preparation of the silico-fluorides from Derbyshire spar. The substances are not new to me. I have had long acquaintance with them, except that of the silico-fluoride of ammonium ($(\text{NH}_4)_2\text{SiF}_6$), which easily dissolves in water. Silico-fluoride of potassium, K_2SiF_6 , or "Salufer," silico-fluoride of sodium, Na_2SiF_6 , and silico-fluoride of calcium, CaSiF_6 , were also sent me by Mr. Mills, with fluor-hydrate of sodium, $\text{NaF}_2\cdot\text{H}_2\text{O}$.

In bringing to bear upon these what little chemical knowledge I could, there were two ways in which I thought one or other of the preparations likely to prove valuable from the standpoint of utility—namely, (1) as a pest destroyer, and (2) as a plant nutrient—a combination which I hold to be imperative in these times of severe competition; therefore I merely satisfied myself of the killing value of the silico-fluoride of sodium and the fluor-hydrate of sodium, thus narrowing the thing down to the ammonia, potash, and lime preparations.

Having a study of eelworms in hand, and fine specimens to operate on, I subjected a few to various solutions in water and in soil, also in the infested tissues of plants. The results were very disastrous to these, and I came to the conclusion, rightly or wrongly, that the preparations were not suitable for use on the living parts of plants, especially foliage. This would, perhaps, have led many cultivators to abandon the articles. I, however, found that 1 oz. of either preparation per square yard would kill eelworms in the soil without injuring this for the purpose of plant growth.

The matter was thus resolved into a very simple affair, as the preparation, in the finest possible powder, could be used before sowing seeds or setting plants as a disinfectant and fertiliser at the rate of $302\frac{1}{2}$ lbs. per acre, $30\frac{1}{4}$ oz. per rod, or 1 oz. per square yard, leaving on the surface or only very lightly harrowing or raking in, as in the operations of drilling in seed. In no case should the substance come into contact with the seed or plant in the dry or powdered form. If desired, the article could be used in solution, 1 oz. to 1 gallon of water, and this quantity applied per square yard.

AN INTERESTING TRIO.

The three articles—(1) *silico-fluoride of ammonium*, (2) *silico-fluoride of potassium*, (3) *silico-fluoride of calcium*—killed eelworms, whiteworms, and slugs in the experimental plats, as ascertained by microscopic examination of soils and soil-waters, and of the three substances the silico-fluoride of ammonium most benefited the plants, these being selected of kinds the most liable to eelworm attacks in the several forms, such as stem-eelworm (*Tylenchus devastatrix*) on Clover and Onions; root-stem eelworm (*T. obtusus*) on Cucumbers and Vines; root-knot eelworm (*Heterodera radicola*) on Tomatoes, and seggling eelworm (*H. Schachtii*) on Hops and Sugar Beet. These pests, every one, lead free as well as parasitic modes of life, and the time to act upon them effectively is during their existence as eggs or larvæ while bathed in the organic solutions of the soil, and on which they unquestionably subsist in free state, being invariably associated with the debris of crops or vegetable remains decaying or decomposed.

On these points I have thoroughly satisfied myself by repeated investigations, and also that the time to destroy eelworms, whiteworms and slugs is when the land is bare. It can be done by lime, kainit, and nitrate of soda in a slow manner, in conjunction with thorough cultivation and due regard to the rotation of crops. About that there can be no question, for most ailments have origin in cultural errors and mistakes or procedure on lines antagonistic to the laws of health required by and essential to the growth, development, and maturity of the particular plant.

Prevention, not cure, should be the great objective of cultivators. To prevent any disease caused by vegetable or animal parasite means must be taken to kill the spores or eggs. This can be done in various ways, invariably whilst outward or exterior of the plant, for nothing applied

externally can have any effect on an organism in living tissues without absorption into them, and then the substance may prove as deleterious to the host as destructive to the parasite. That marks the difference between prevention and remedy. If eelworms, whiteworms, or slugs are in the soil the time to kill them is when there is no danger of prejudicing the current or proposed crop. Silico-fluoride of ammonium can be used much more freely than when the land is under crop; but I consider, according to the experimental data, that the amount quoted would be sufficient for general purposes, or in bad cases it could be doubled, this being matter for further investigation; suffice at present that the strength named for killing the pests be given as found.

ACTION AND RESULTS.

The silico-fluoride of ammonium dissolves in rain water, and at a strength of 1 oz. to 1 gallon of water kills eelworm in a short time. It does not appear to injure the roots of Tomatoes when applied to the soil, as in an ordinary watering, with the soil in a moderately moist condition when the solution is supplied. At the strength quoted it seems too strong for Cucumbers, but a solution of 1 oz. to $1\frac{1}{2}$ gallon of water had no injurious effect on the roots. At that strength, 1 in 240, the solution also kills eelworms, but requires a longer time. In both cases the eelworms collapse in the tissues, and these also succumb. That is where the difficulty comes in—nothing will restore destroyed tissues. The plants may die, or they may live after treatment, for all depends upon the extent of the damage inflicted by the eelworm, and possibly also by the deleterious action of the solution on the cells in contact with the damaged parts. The latter are quickly saturated by the solution, but that of imbibition by adjacent living cells is quite another matter, and depends partly on the plant itself and in part on the substance.

The action of the silico-fluoride of ammonium is corrosive. It kills pests by that process. The effect on slugs is a sight to see once only, and never desire to behold again, for they simply appear to boil by the chemical action of the powder. Eelworms perform their graceful evolutions in the vain endeavour to escape, and soon assume needle form. Whiteworms (*Enchytræus* sp.) seldom make more than a wriggle to right and left, and die. In a 1 in 1000 solution, 1 oz. silico-fluoride of ammonium to $6\frac{1}{4}$ gallons of water, the pests named succumb in the course of time, but whether that would suffice as a general preventive, applied in the ordinary course of watering, remains to be tested, and the most that I am prepared to say is that it would probably answer that purpose, and also as a repressive measure in the early stages of attack. This never occurs when the free eelworms are bathed in a solution hurtful to them, as they make "tracks" away from such soil as fast as possible.

MANURIAL PROPERTIES AND COST.

Of the value of the article, silico-fluoride of ammonium, as a manure, it may be said that it contains over 19 per cent. of ammonia, therefore almost equal in that respect to ordinary sulphate of ammonia, and while the land would be disinfected by a suitable top-dressing, and practically freed from pests, the ammonia would remain for the benefit of the crop. According to Mr. Mills' former article the cost would be £1 per cwt., or 10s. cost for killing the eelworm, and 10s. value as manure, per each cwt. applied. On this point, however, time only can give anything warrantable, and experiments in that direction must rest with cultivators.

The silico-fluoride of potassium has, so far as I have tested, more decisively anti-fungoid properties than the ammonium preparation, also that of calcium, but the sodium, if anything, tends to favour cryptogamous parasites by its action on the tissues of the hosts. What would be the difference in cost of silico-fluoride of ammonium over the silico-fluorides of potassium and calcium I do not know. Perhaps Mr. Mills will supply particulars in those respects. I shall not continue further experiments at present, as my material has become exhausted, the eelworms having departed—I may say that the silico-fluorides appear to advantage in the experiments as disinfectants of land foul with root-pests. In other respects the articles would probably usefully aid the plant by fortifying it with material resistive of invasion by enemies; at least such are the deductions from the experiments.—G. ABBEY.

CLEANSING WALL TREES.

EFFORTS must be made to cleanse wall trees if the shoots are infested with black or green aphids. Cherries, Plums, Peaches, Nectarines, and Apricots are the most liable to attacks from these insects. Cold winds and checks to growth, as well as lack of moisture for the root system, are conducive of attack. In cold, dull weather the syringe or water engine is not employed so freely on wall trees, hence insects gain a foothold and increase freely under undisturbed conditions.

Dusting with tobacco powder is efficacious when the pests are first noticed. On becoming a numerous colony, a strong application of some approved insecticide is needed. A bitter solution not only destroys them, but renders the foliage distasteful to fresh broods seeking to become established. Quassia chips boiled and the solution combined with dissolved softsoap, forms a serviceable mixture, but it is not superior to the prepared quassia extract which can be procured ready for use, only requiring mixing with water at the rate of 20 gallons of water to a quart of extract.

It is important that Cherry trees be freed from these pests before the fruit commences colouring, and all trees infested are better for being cleansed as soon as possible. It is often delayed too long with disastrous results.—A KENTISH GARDENER.

HARDY BULBS—A REVIEW.

MOST of our hardy bulbous plants have now shed their beauty, and while they continue to provide substance for another floral issue next season, we may profit by a little meditation on what they have been, or may be made to become, as garden ornaments in the future.

The past winter was a mild one, and our various winter and spring flowers had a good chance to display their charms. Among the first of bulbous plants in flower was *Crocus Imperati*. So early as the 6th of January a small bed was adorned with its flowers. The petals were deep lilac on the inside, and on the outside, seen when the flowers closed, they were paler lilac and distinctly striped with a deep mauve. In a similar bed there was another species, *Crocus chrysanthus*, in bloom. This, as its specific name implies, is of a golden yellow colour, and formed a good contrast to *Imperati*. The various forms of *C. aureus* and *C. biflorus*, planted with the bulbs a few inches apart on mounds or banks, give a fine effect in the middle and end of February. The numerous varieties of *C. vernus* and *C. versicolor* also do well in such places. We may look forward and expect the autumn-flowering species, amongst the best being *C. iridiflorus*, *C. nudiflorus* and *C. speciosus*.

As regards the Snowdrop, *Galanthus nivalis*, there is little need for comment, but an opinion may be given with regard to planting in places to produce a good effect. This year I noticed several beds crowded with Snowdrops, and thought such an arrangement unsatisfactory. It seemed too extravagant to be beautiful. A better plan was exemplified in another bed. In it the Snowdrops appeared in small clumps under the Lilac shrubs with which the bed was planted. The bare stems of the Lilacs formed a sort of network as a light veil for the pure beauty of the Snowdrops behind, and the graceful form of the individual flowers was better shown than in the mass of white in the other bed; also when planted in small clumps about old tree stumps near trailing Periwinkle or Ivy they looked quite at home.

Eranthis hyemalis, the Winter Aconite, although not strictly a bulbous plant, for it has tubers instead of bulbs, is worthy of notice. Forming the groundwork of a bed of small deciduous shrubs, this plant with its bright yellow flowers was highly effective, and that so early as January 21st.

In the rockery in February patches of *Bulbocodium vernum* brightened corners with its violet purple flowers. Here also, as well as in beds, the little blue *Scilla sibirica* compelled admiration. About the beginning of March we had *Chionodoxa Luciliae*. Its bright blue flowers with a white eye in each look well in almost any position; but as groundwork for a bed of shrubs or in large thin patches on a grassy bank, it appears most effective. A large bed of *Forsythia suspensa*, with the *Chionodoxa* for a groundwork, formed quite a picture in the middle of March. The bright blue and white flowers harmonised well with the yellow flowers of the *Forsythia* on the long slender branches.

With regard to *Narcissus*, I think the review must be very general—a mere glance, for the genus affords scope for pages of writing. The good old Daffodil, *N. pseudo-Narcissus*, shows its fine yellow trumpet-bearing flowers early in March. It is a native of Britain, and has been well known for a long time, so it scarcely needs comment here. In large clumps on a rising ground its beauty is as well seen (if not planted thickly) as it is dotted about the outside of a shrubbery. The garden forms of this species are legion, which we may notice as we glance through the hosts of varieties of *Magni*, *Medio*, and *Parvi-coronati* groups in any good treatise on the genus.

N. incomparabilis also flowers in March. It looks well in the same positions as the foregoing species, and its orange yellow crowns and paler yellow perianth divisions make it a worthy successor to the Daffodil. The double form of the whitish variety of this species, sometimes called Orange Phoenix, is occasionally seen in gardens. Another double form is commonly called Butter-and-Eggs, which name conveys an idea of its colour. This poor plant has the misfortune of bearing a long name, which, when given in full, is *Narcissus incomparabilis aurantius flore pleno*.

The Jonquil, *N. Jonquilla*, is a neat plant, and with its small bright yellow flowers in clusters of four to six on each scape is worthy of a place on the grass round the edge of a shrubbery. Its worth is enhanced by the sweet scent of its flowers. The Poet's Narciss, or Pheasant's Eye, *N. poeticus*, is a well known species, and one of the sweetest of the genus. It has a few good varieties, varying partly in their period of flowering, *recurvus* being a late one and *poetarum* an early one. *N. bulbocodium* is a very distinct species. In shape the flower resembles a crinoline skirt, an old time vulgarity. Its colour is a bright yellow, and it looks well in a sheltered corner of the rockery. The variety *monophyllus* is worthy of mention; in it the corona and perianth are paler in colour than the type—indeed, they are almost white.

The Hyacinth may next be dealt with. Most of the garden varieties originated in one species, *H. orientalis*. There is a species called *H. romanus*, which is not, however, the Roman Hyacinth as known in gardens. The latter is really a variety—i.e., *albulus*—of *H. orientalis*. The qualities of the numerous varieties now in cultivation can best be comprehended by perusing the special literature on the subject. I have noticed during the past season a decline in the popularity of this plant for garden decoration. This may be partly due to the wonderful development of *Narcissi* and *Tulips* which seemed to claim the admiration of everyone.—EXCELSIOR.

(To be continued.)

YORK HORTICULTURAL SHOW.

JUNE 15TH, 16TH, AND 17TH.

LAST year's York Gala will ever be memorable in the horticultural world, because it was then that the whole of the tents were blown to ribbons in the gale that raged on the morning of the first day of the show. It will be remembered that it was the occasion of an enormous amount of damage, not only to the tents themselves, but also to many of the valuable plants therein contained. This year, happily, there was no such catastrophe to record. On the contrary, the opening day was a lovely one, the weather being fine without being oppressively hot. This was very advantageous, as the number of people who visited the exhibition during the afternoon were able to examine the multifarious products in some degree of comfort, which is by no means always the case at exhibitions of this character. The several tents were all most spacious, and locomotion was fairly comfortable throughout the whole of them, except, perhaps, in one or two congested spots.

It would be manifestly unfair to endeavour to make any comparison between this season's show and that of last year, on account of the occurrence just noted, and such will not therefore be done. We may, however, compare other seasons, and when we do so we find the majority is firmly of the opinion that, taken as a whole, there is a decided advance, though one or two sections are distinctly inferior to what has become the custom, Roses being particularly so. There was scarcely any competition throughout, and there were few first quality blooms staged. This was the cause for much regret, as the York Roses have on occasions been amongst the finest at any provincial show, and this, notwithstanding the earliness of the Gala dates. The weather, that all-important factor in the horticultural world, has been by no means conducive to the production of early Roses, and York will not be the only sufferer from this cause. Fruit, too, was not quite up to the standard, but the groups and other portions of the exhibition were very fine indeed, and a credit to their growers and staggers.

The planning of the several marquees, so as to produce the best general effect, had been done skilfully, but points were lost here and there which rather marred the spectacle. Then, too, there is plenty of room for improvement in the placing of the individual exhibits in any particular class, which appears to be left entirely to the discretion of the exhibitor, with the result that different entries were often yards apart. If this benefited the display it could be understood, but where nothing is gained in this respect we can see no object in doing it. As a result of this we were unable to find a few of the classes, and can only give notes of those that were seen. We might point out to the Gala Committee that the officiousness and incivility of some of the officials of the show were both annoying and unwise, and at the same time we would accord a word of thanks to Sir Christopher Millward for his unfailing courtesy, and his readiness to render any necessary assistance.

GROUPS AND SPECIMEN PLANTS.

The premier position for a group of miscellaneous plants in or out of bloom, arranged for effect, and occupying a space not exceeding 300 square feet, was secured by Mr. C. J. Mee, Nottingham. The arrangement was a very charming one, though the effect was slightly marred by an immense *Kentia Belmoreana* in the front. The mossed surface was undulating, and as specimens here and there *Crotons* were admirably employed. *Odontoglossums* were effective, as were *Begonias*, *Anthuriums*, *Palms*, *Ferns*, *Cypripediums*, and others. Mr. J. Wilson, gardener to Sir Jas. Reckitt, Bart., Swanland Manor, who secured the second place, had a very similar arrangement. The plants, however, were not so lightly or gracefully arranged, though they were skilfully chosen and finely grown. It must have been a difficult matter to decide the respective positions of these. Mr. J. McIntyre, gardener to Mrs. Gurney Pease, Woodside, Darlington, occupied the third position, but though fine plants were employed, it lacked the characteristic features of the other two. The fourth position went to Mr. W. Vause of Leamington, and the fifth to Messrs. R. Simpson & Son, Selby.

In the class for ten stove or greenhouse plants in bloom and six foliage plants Mr. Jas. Cypher, Cheltenham, went to the front with his unique plants. The specimens were *Pimelea diosmaefolia*, *Erica Cavendishi*, *Clerodendron Balfourianum*, *Phenocoma prolifera* Barnesi, *Erica depressa*, *Stephanotis grandiflora*, *Anthurium Wardi*, *Bougainvillea Cypheri*, *Erica hirsuta alba tinctoria*, *Franciscea eximia*, and *Erica ventricosa magnifica*, with *Kentia australis*, *Cycas undulata*, *Latania borbonica*, *Kentia Belmoreana*, *Phoenix rupicola*, and *Kentia Fosteriana*. Mr. F. Nicholas, gardener to the Marquis of Zetland, Marske-by-the-Sea, was a very creditable second, his specimens of *Erica depressa multiflora*, *Azalea Duc de Nassau*, *Aphelaxis rosea*, and *Croton angustifolium* being very fine. The third position was assigned to Mr. W. Vause, who grows specimen plants so well. Mr. J. Cypher was again ahead for six specimen plants in bloom, showing *Pimelea diosmaefolia*, *Bougainvillea glabra*, *Aphelaxis macrantha rosea*, *Anthurium Scherzerianum*, *Clerodendron Balfourianum*, and *Erica depressa*. Mr. Chas. Lawton, gardener to H. Harrison Broadley, Esq., Welton House, Brough, was a splendid second; and Mr. W. Vause third.

Mr. J. Sunley, Milford Junction, went to the front for three specimen plants in flower with *Genetyllis tulipifera*, *Anthurium Scherzerianum*, and *Erica ventricosa grandiflora*. Mr. Lawton was second. For a single specimen stove plant in bloom Mr. C. J. Mee was first with *Anthurium Scherzerianum*; Messrs. R. Simpson & Son second with *Stephanotis floribunda*; and Mr. J. R. Rollinson, gardener to W. Bateman, Esq., Pannal, Leeds, third with *Anthurium Scherzerianum*. Mr. W. Vause was first with *Aphelaxis macrantha rosea* in the class for a single greenhouse plant

in bloom, and was followed by Mr. G. Dobson, gardener to R. Lawson, Esq., Clifton, York, with *Hydrangea hortensis*, who took second prize.

Mr. J. McIntyre was well ahead for six foliage plants with *Croton* Queen Victoria, *C. angustifolia*, *Cycas sinensis*, *Kentia Fosteriana*, *K. Belmoreana*, and one other. Mr. Lawton was a splendid second prize winner. The third place was adjudged to Messrs. R. Simpson & Son, and the fourth to Mr. W. Vause. Mr. J. McIntyre was again first for three foliage plants with *Croton Warreni*, *Cycas revoluta*, and *Kentia Belmoreana*. Mr. W. Townsend, gardener to E. B. Faber, Esq., was second; and Mr. C. Lawton third.

For three Azaleas Mr. J. Sunley, with admirably flowered plants, was first, and was apparently the only exhibitor. Mr. J. Cypher won with a single Azalea, and was followed by Messrs. W. Jackson & Co., Bedale, and Mr. J. R. Rollinson, who were second and third respectively. Mr. J. McIntyre had grand plants of *Crotons* in the class for four, and was followed by Messrs. R. Simpson & Son and Mr. C. Lawton, who were second and third respectively. Mr. J. Cypher was first for three Cape Heaths with *depressa*, *affinis*, and *ventricosa grandiflora*. Mr. C. Lawton secured second place, and Mr. J. Sunley third.

For six exotic Ferns Mr. J. McIntyre had excellent specimens of *Adiantum Mariessi*, *Microlepia hirta cristata*, *Davallia fijiensis*, and *D. Mooreana*. Mr. J. Snowden, gardener to the Rev. G. Yeats, Heworth, was a very good second. Mr. J. McIntyre was also first for three Ferns with *Davallia fijiensis*, *D. Mooreana*, and *Gleichenia rupestris glaucescens*. Mr. F. Nicholas was a very creditable second, and Mr. J. Snowden third. The last named exhibitor was first for a single Fern with *Adiantum farleyense*. Mr. J. McIntyre was second with the same, and Mr. F. Nicholas third with *Lomaria zamiaefolia*.

In the class for ten hardy Ferns, distinct, the competition was not very keen. Mr. J. Nicholson, Bootham Stray, York, being first with fine specimens of *Trichomanes radicans*, *Adiantum pedatum*, *Osmunda cristata*, and others. Messrs. R. Simpson & Son were placed in the second position. Messrs. J. Nicholson and R. Simpson & Son maintained the same position for six hardy Ferns, and were followed by Mr. J. Snowden.

ORCHIDS.

The Victoria prize for a group of Orchids in bloom, arranged for effect, occupying space not exceeding 150 square feet (Palms and Ferns were admissible), was secured by Mr. J. Cypher, who showed in his customary splendid style. Not only was there excellence in the quality of the Orchids utilised, but the arrangement of them showed consummate skill. Mr. J. Robson, Altrincham, was second, but while the flowers were of fine quality, the arrangement lacked the grace of the premier group.

For ten Orchids Mr. Jas. Cypher held the foremost position with handsome specimens of *Lælia purpurata alba*, *Thunia Veitchi*, *Cattleya Warneri*, *Odontoglossum hystrix excellens*, *Cattleya lobata*, *Epidendrum prismatocarpum*, *Lælia tenebrosa*, *L. purpurata Schofieldiana*, and *Cattleya Mossiae*. Mr. Barker, gardener to W. P. Burkenshaw, Esq., Hull, was a creditable second; and Mr. W. Townsend third. Mr. J. Cypher was also first for six and three Orchids, and Mr. C. Lawton for one plant with a grand specimen of *Lælia purpurata*. In the amateurs' class for six Orchids Mr. Barker was a fine first, as was he in the special class for four Orchids, the prizes being given by Messrs. Backhouse & Son, York.

PELARGONIUMS AND FUCHSIAS.

Mr. R. McIntosh, gardener to J. T. Kingston, Esq., Clifton, York, sent superb examples in the class for twelve Show Pelargoniums. The plants were perfect examples of culture, and such as are seldom seen. The varieties comprised *Garibaldi*, *Miss Winnie Kingston*, *Madame Thibaut*, *Madame Hilare*, *Lady Isabella*, *Kingston Beauty*, *Rose Queen*, *Triomphe de St. Mandé*, *Duchess of Bedford*, *Edward Perkins*, *Queen Bess*, and *Tommy Dodd*. Mr. I. Eastwood, gardener to Mrs. Tetley, Foxhill, Weetwood, secured second place, and also staged remarkable plants. These two were the only exhibitors in the class. The same position was maintained in the class for six specimens, but was reversed for three plants.

Mr. H. Pybus, Ripon, exhibited superb specimens in the class for six Ivy-leaved Pelargoniums, the varieties *Prince of Wales*, *Beauty of Castlehill*, and *Souvenir de Chas. Turner* being the best. Mr. I. Eastwood was second, and Mr. R. McIntosh third. Mr. Eastwood was first for three Ivy-leaved Pelargoniums with superior plants. The second prize went to Mr. H. Pybus, and the third to Mr. G. Cottam, Cottingham. Mr. I. Eastwood was first for three double Pelargoniums, Mr. H. Pybus being second, and Mr. G. Clarke, gardener to Miss Wharton, York, third.

In the class for nine double Pelargoniums Mr. I. Eastwood was a decided first, though Messrs. R. Simpson & Son, who were second, showed very finely. Mr. I. Eastwood was in great form in the class for twelve Zonal Pelargoniums, his specimens being superb. The trusses of flowers were large, as were the individual pips. Mr. H. Pybus was second in this class, and first for six plants, showing well in each instance. Mr. J. Eastwood had to be content with second position, but went ahead of Mr. Pybus again in the class for three Zonals.

Mr. G. Clarke took the premier award for three splendid Fuchsias, the plants being of fine form and well flowered. Mr. R. McIntosh was a creditable second, and Mr. I. Eastwood third. For six specimens Mr. R. McIntosh went to the front in good style, and was followed by Mr. I. Eastwood and Mr. G. Clarke in the order in which the names are given.

BEGONIAS, CARNATIONS, AND ROSES.

Mr. J. Haigh, gardener to G. P. Kirby, Esq., York, was a decided first for eight Begonias with well flowered plants; Mr. G. Clarke was second, and Mr. T. Douthwaite, gardener to Miss Barstow, Garrow Hill, York, third. Messrs. R. Simpson & Son and G. Clarke were the only exhibitors in the class for a group of Begonias, neither showing anything specially praiseworthy.

Mr. Jas. Tullett, gardener to Lord Barnard, Raby Castle, Darlington, was the only exhibitor in the class for a group of Carnations. He was accorded the premier award, and the Malmaisons, of which the group was mainly composed, deserved this honour. For twelve Gloxinias Mr. G. Dobson was first with good plants, and was followed by Mr. W. Fletcher, gardener to T. M. Lambert, Esq., York, and Mr. W. Spavin, gardener to J. Bellerby, Esq., York, in the order named. Mr. W. Fletcher was first for eight fine *Calceolarias*. Mr. E. Everard, gardener to Mrs. Gutch, York, was second, and Mr. W. Spavin third.

The class for a collection of Roses in pots did not bring forth anything particularly praiseworthy. Messrs. W. Jackson & Co. were first, and Mr. H. Pybus third, there being apparently no second prize awarded. In the class for nine Roses in pots, Messrs. W. Jackson & Son were first, Mr. H. Pybus second, and Mr. I. Eastwood third. For seventy-two cut blooms, in not less than thirty-six varieties, Messrs. J. & A. May, Bedale, were first, their best blooms being *Ulrich Brunner*, *Gustav Piganeau*, *Maréchal Niel*, *Mrs. J. Laing*, *Niphetos*, *The Bride*, *Caroline Testout*, *Fisher Holmes*, *Marie Verdier*, *Suzanne Marie Rodocanachi*, and *Marie Van Houtte*. Mr. G. Mount, Canterbury, with smaller flowers, was second.

For forty-eight distinct single trusses, Mr. G. Mount was decidedly first, though his flowers were by no means up to the Canterbury grower's usual form. Messrs. J. & A. May were second, and the same order was maintained for thirty-six distinct single trusses; but again the stands were weak. Messrs. J. Burrell & Co., Cambridge, were first for twenty-four distinct Roses, the blooms of *Catherine Mermet*, *A. K. Williams*, *The Bride*, *Horace Vernet*, *La France*, and *Innocente Pirola* being good. Mr. G. Mount was second, and Messrs. J. & A. May third. Messrs. J. Burrell & Co. and G. Mount were first and second for eighteen varieties, Mr. W. Hutchinson, Kirby Moorside, being third.

For twelve white and yellow Roses, in not less than six varieties, Mr. G. Mount was first with *Maréchal Niel*, *Anna Ollivier*, *Niphetos*, *Caroline Kuster*, *Perle des Jardins*, and *Marie Van Houtte*. Messrs. J. & A. May were second, and Mr. W. Hutchinson third. In the amateurs' classes for twelve and eighteen Roses respectively, Messrs. W. Hutchinson, I. Eastwood, J. Mallender, Worksop, and J. Hume, Clifton, were the chief prize-takers.

CUT FLOWERS.

Messrs. Perkins & Sons, Coventry, were easily first with a hand basket of cut flowers, open. Mr. Geo. Webster, Sunderland, was second; and Mr. Wm. Vause, Leamington, third. Messrs. Perkins & Sons were first with their hand basket of cut flowers (Orchids excluded), bridal bouquets, and for ball bouquets; being followed by Messrs. Webster, Vause, and Cotham, Cottingham. Pansies were not extensively shown. The first prize for forty-eight Fancy Pansies was taken by Mr. John Smellie, Busby, Glasgow; Mr. M. Campbell, Blantyre, N.B., taking the second prize. Mr. M. Campbell was first for twenty-four Fancy Pansies. In the other classes Messrs. Campbell, Smellie, and Mr. Ramsden, Halifax, took the remaining prizes.

FRUIT

With but few exceptions there was a deficiency of colour in the Peaches and Nectarines shown. White Grapes, too, were not up to the usual high standard one has been accustomed to see at York. Some well-finished bunches of Black Hamburgs were shown. Mr. J. Tullett, gardener to Lord Barnard, Raby Castle, Darlington, was first with a decorated table of ripe fruit. His exhibit comprised well-finished Black Hamburg and good bunches of Muscat of Alexandria Grapes, that required a little more time to finish them, a small Pine Apple, Royal George Peach, Lord Napier Nectarine, Royal Sovereign Strawberry, Bananas, and Figs. The decoration of this table was superb, Mr. Tullett relying chiefly on *Odontoglossum Alexandræ* and *Asparagus plumosus*, a few Grasses being lightly distributed throughout the whole. Mr. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, was second. This exhibitor had the best dish of Royal Sovereign Strawberry in the show. Mr. McIndoe, gardener to Sir J. W. Pease, Hutton Hall, was third. This exhibitor had the best dish of Lord Napier Nectarines on his table in the show. The competition between the last two exhibitors was very close, but eventually Mr. Goodacre was placed second by only a few points. Mr. J. Sinclair, Blake Street, York, obtained fourth prize. The flowers used in the decoration of this table were yellow Iris.

Mr. McIndoe was the only exhibitor of six kinds of fruit, and was deservedly awarded the first prize. It consisted of Black Hamburg and Foster's Seedling Grapes, a Melon, and Peaches. Mr. McIndoe was also first with four dishes, showing Black Hamburg Grapes, Scarlet Premier Melon, Stanwick Elruge Nectarine, and Brown Turkey Figs. Mr. Easter, gardener to Lord St. Oswald, Nostell Priory, Wakefield, was a good second. The third prize went to Mr. Goodacre, Lord Lathom being awarded fourth prize.

For three bunches of Black Hamburg Grapes, Mr. Jas. Johnson, Boston Spa, was an easy first with good bunches, having large well finished berries; Mr. Leadbetter second; Mr. J. Tullett third, and Mr. Alsopp, gardener to S. J. Foljambe, Esq., Osberton, Worksop, fourth. Mr. J. Tullett was first with white Grapes, showing large bunches of Foster's Seedling; Mr. Nicholls, gardener to Lady Beaumont, Carlton Towers, second with Buckland Sweetwater; Mr. G. Wilson, gardener to Sir Jas. Reckett, Bart., Swanland Manor, Brough, third.

The first award for six Peaches went to Mr. A. Alderman, gardener to J. D. Ellis, Esq., Worksop, who showed fine fruit of Hale's Early; Mr. J. Easter was a close second, and Mr. J. Wallis, gardener to Ralph Sneyd, Esq., Keele Hall, was third. Mr. Pike, gardener to C. H. Wilson, Esq., Warter Priory, was awarded first prize for six Nectarines, the variety being Lord Napier; Mr. Goodacre was second with the same variety; Mr. Slade, gardener to the Duke of Newcastle, Clumber, Worksop, third,

and Mr. J. McIndoe, fourth. Mr. J. McIndoe was first for a scarlet fleshed Melon, Mr. Goodacre was second, and Mr. F. Steadman, gardener to Colonel Thorpe, Coddington Hall, Newark, third.

Mr. Ashton, gardener to the Earl of Lathom, was first and second in the class for green-fleshed Melons; Mr. J. McIndoe third. Mr. Slade was first with a white-fleshed Melon, Mr. F. Steadman second, Mr. J. McIndoe third. For a dish of Figs Mr. A. F. Pike was first, Mr. J. P. Leadbetter second, Mr. J. Wallis third.

There were only two exhibitors of Strawberries, Mr. A. Alderman being an easy first with Royal Sovereign; Mr. G. A. Keywood, gardener to W. H. Battie-Wrightson, Esq., Cusworth Hall, Doncaster, second. Mr. Slade was first for a dish of Tomatoes, showing grand fruit of Perfection; Mr. A. H. Hall, gardener to J. C. Waterhouse, Esq., Prestbury, second; Mr. Nichols and Mr. Keywood being third and fourth.

VEGETABLES.

Messrs. Sutton & Sons, Reading, and Messrs. Webb & Sons, Stourbridge, offered valuable prizes for collections of vegetables, Mr. J. McIndoe taking first in each class, Vegetable Marrows, French Beans, and Peerless Marrowfat Peas being very good. Mr. S. Mortimer, Farnham, Surrey, received an award of merit for his new Cucumbers Sensation (Telegraph type) and The Keeper, a black spine variety.

MISCELLANEOUS EXHIBITS.

The groups of plants staged by various growers in the "not for competition" section were numerous and diversified, showing excellent culture, and, in many instances, great taste in arrangement. Messrs. J. Veitch and Sons, Ltd., Chelsea, sent an exhibit of considerable size, which comprised many kinds of plants. The firm's superb Caladiums were a show in themselves, the delicately tinted leaves being very handsome. Prominent amongst the varieties were candidum, Assungay, Leonard Bause, Silver Queen, Miss Ellen Terry, and Exquisite. In the mixed plants, *Dracena Exquisite*, hybrid *Rhododendrons*, *Streptocarpus*, *Crotons*, *Carnations*, *Begonias*, and *Palms* were fine. The Chelsea firm was, as usual, in strong force with *Orchids*, which were grandly shown. The flowers and plants were of excellent quality, the colours being very rich. Such as *Cattleya Mossiae Reineckiana superba*, *C. Mendeli virginialis*, *Disa Veitchi*, *Laelia purpurata*, *Laelio-Cattleya Canhamiana*, *L.-C. Hippolyta*, with *Cypripediums*, were particularly conspicuous.

One of the most effective exhibits in this section was that shown by Messrs. W. Cutbush & Son, Highgate. The surface was undulating, and the excellent plants comprised dwarf specimens of *Malmaison Carnations* carrying good flowers, *Lilium Harrisii*, *Crimson Rambler Roses*, *Cannas*, *Azaleas*, *Hydrangeas*, *Ericas*, *Palms* and *Ferns*. *Caladiums* from Messrs. J. Peed & Son, West Norwood, were very beautiful, and were capitally arranged for effect. Light varieties, such as *Leonard Bause*, *Lord Derby*, *Duchess of Teck*, *Mrs. W. E. Gladstone* and *Silver Cloud* were interspersed amidst such darks as *John Peed*, *Maria Mitjana*, *Duke of Teck*, and others. Single and double *Begonias* also came from Norwood, the former being especially fine. *Gloxinias* and *Streptocarpus* in trays completed the group.

Differing entirely from every other group in the show, and gaining in effectiveness thereby, Messrs. Fisher, Son, & Sibray, Ltd., Handsworth, Sheffield, are to be congratulated on their exhibit. About 900 square feet were occupied with well diversified plants. A bank of *Rhododendrons* was handsome, and the specimens were capitally arranged to appear as natural as possible. The trusses were grand. Of the foliage plants *Japanese Maples*, *Pyrus aria himalaica*, *Purple Oaks*, with bunches of the best forms of *Lilacs* included, were charming. The firm sent also miscellaneous stove and greenhouse plants, such as *Anthuriums*, *Nepenthes*, *Crotons*, *Caladiums*, *Begonias*, *Bertolonias*, *Palms*, *Ferns*, and others. The new *Croton Her Majesty* showed up well, as did *Dracena Veitchi variegata*.

The whole central table in one of the tents was occupied by Messrs. Sutton & Sons, Reading, with one of their customary displays of flowers and vegetables in pots and boxes. Tomatoes were grand trained in single stem and other forms. *Prince of Wales*, *Peachblow*, *Abundance*, *Sunbeam*, and *Princess of Wales* were particularly effective. No less superior were the Peas, which included *Early Giant*, *Perfection*, *Sutton's Forcing*, *Excelsior*, and others. The excellence of the Reading *Gloxinias* has long been recognised. The strain is extremely floriferous, and the colours range from pure white to rich crimson and blue. Spotted varieties were numerous, as were the scarlet selfs. Some fine *Mignonette* completed the stand.

Miscellaneous cut flowers and plants comprised the large group sent by Messrs. R. Smith & Co., Worcester. Specimen *Clematis* were, needless to say, fine, as were *Roses* in pots, *Hydrangeas*, *Pyrethrums*, *Irises*, *Begonias*, *Pæonies*, and many others, backed by graceful *Bamboos*. The hardy herbaceous flowers from Messrs. Dickson, Ltd., Chester, were shown effectively in medium sized bunches. Very good were *Spanish* and *German Irises*, *Liliums*, and single and double *Pyrethrums*, *Armerias*, *Sparaxis*, *Primulas*, *Pæonies*, *Poppies*, and *Muscari*. *Carnation Duchess Consuelo* also came from the Chester firm. Mr. G. Yeld, Clifton Cottage, York, sent some plants of his own raising, the *Irises* being particularly good. *Dawn*, *Hera*, and *Sincerity* were splendid, as were *Hemerocallis Stella* and *Apricot*.

Pyrethrums formed the backbone of the group from Messrs. W. Clibran and Son, Altrincham, and they were of good quality, both in single and double varieties. *Irises* were also noted, as were *Pæonies* and *Violas*, arranged in flat trays. Messrs. Jarman & Co. sent from Chard *Rhododendrons*, *Roses*, *Poppies*, *Pyrethrums*, *Pæonies*, and others. *Ferns* from Messrs. W. & J. Birkenhead, Sale, were cool and refreshing in the warm tents, amidst the many brightly flowered hardy plants and *Orchids*. The kinds and varieties were exceedingly numerous, and all bore the impress of good culture. The major portion were growing in about 3-inch pots, though a few were in larger sizes and baskets. Mr. Amos

Perry, Winchmore Hill, sent herbaceous flowers in variety. Mr. W. Sydenham, Birmingham, showed a table of flowers in silvered receptacles, with which a charming display was effected. Such simple flowers as *Carnations* and *Sweet Peas* were employed, with *Ferns* and *Smilax* for greenery. Messrs. H. Low & Co. Bush Hill Park, showed a fine bank of *Orchids*, in which forms of *Cattleya Mossiae* were numerous and wonderfully rich in colour. Varieties of *Odontoglossum crispum* were well shown, and the same may be said of the *Cypripediums*, *Dendrobiums*, and *Oncidium*s; but these were in much smaller numbers. Very charming were *Cattleya Mossiae* E. Ashworth, C. M. Wagneri, and C. M. Arnoldiana, with *Cypripedium Lawrenceanum Hyeanum*.

Messrs. B. S. Williams & Son, Upper Holloway, exhibited *Orchids* arranged with *Ferns* and other foliage plants. The arrangement was very good, a charming effect being produced. Conspicuous amongst the *Orchids* were *Cattleyas*, *Cypripediums*, *Odontoglossums*, *Dendrobiums*,

FIG. 99.—ASCLEPIAS TUBEROSA.

Vandas, *Thunias*, *Sobralias*, and *Cymbidiums*. *Carnations* were also utilised in one corner of the group. Messrs. Sander & Co., St. Albans, were in first-class form, and their exhibit attracted an immense amount of attention. The splendid *Acalypha Sanderi*, *Dracena Sanderiana*, *D. Godseffiana*, *Laelia tenebrosa*, *Laelio-Cattleya Duke of York*, *L.-C. Lily Measures*, *Odontoglossums*, *Petunia Mrs. F. Sander*, white, and others were noticed.

ASCLEPIAS TUBEROSA.

WE can best give "G. J. R." the information he desires by reproducing the woodcut of this plant, which we do in fig. 99. Comparatively few species of the *Asclepias* are cultivated in borders as hardy plants, and perhaps there are few that are really worthy of a place amongst the many attractive plants now grown in British gardens. No doubt can, however, be entertained respecting the merits of the plant represented in the accompanying woodcut. In warm soils and situations it thrives vigorously, especially if the natural drainage be good, and being readily increased fine clumps can soon be had. The flowers are bright orange-red, and are produced in dense corymbose heads at the tops of the stems, which are clothed with narrow sessile leaves. It forms compact bushy plants, 2 feet or so in height, and it can be increased by seeds or division of the tubers, the latter being preferable and quicker than the other; in fact, seeds are not produced with certainty.

THE YOUNG GARDENERS' DOMAIN.

GLADIOLUS THE BRIDE.

IT will be remembered that a few months ago I contributed cultural notes on these very desirable flowers. I cannot let their flowering season pass entirely without again calling attention to them. I need not say any more regarding their culture, as I presume the notes in question were read, and are perhaps remembered; suffice it to say that the method advised has been all that could be desired. The plants were treated precisely as I recommended, and brought into the conservatory as soon as they were presentable.

The first pot to flower was a 32-size, and contained ten bulbs, having twenty-three fine strong spikes of bloom, the majority of which needed no support. Arranged amongst Zonal Pelargoniums, Calceolarias, Spiræas, and other flowering plants, they are very charming, and for cutting—either for the dinner-table or any other purpose—are almost indispensable. One thing puzzles me about them, the tips of some of the leaves turning yellow. Can any young gardener tell us its cause and prevention? We have been very careful in watering the plants, and I do not think they have been checked in any way. I am of opinion that all bulbous plants require perfect drainage and careful watering, as the least stagnation in the soil very soon causes disease to attack them.—NIL DESPERANDUM.

[If our correspondent had given the date and page on which his former article appeared the present one would have been more complete.]

THE KITCHEN GARDEN.

I CANNOT permit the remarks of "A Young Scot," on page 488, June 9th, to pass unheeded. I do not think he has fairly grasped the meaning of my article on "The Kitchen Garden," page 378, April 28th. It was not meant for those who have had practical training in outdoor gardening; nor for them to take umbrage at. It was well meant, and written in a good spirit, for those young gardeners who, through perhaps no fault of their own, have been cast in a place where the opportunity never offered for them to practically learn the routine of the kitchen garden, and I know only too well there are many such. I had the hope that my article would be an incentive to them to make good use of such opportunities as presented themselves.

A few words as to my "contracted experience" and "intentions to hug the glass houses." Now, "A Young Scot," where can you find that I made any reference to myself or my capabilities? When and where have I stated I have had no practical experience in the kitchen garden? What I have so far contributed to the "Domain" has been the result of practical knowledge. Perhaps you may doubt it, but it is nevertheless true. I am not a believer in "preaching" from theory. My experience has so far been under men of "the old school," one of whom I have the pleasure of serving at present—a man who has the interest of his young men thoroughly at heart, and whose desire it is to see them excel in "all" branches of their calling, not of merely "hugging the glass houses."

As for what opportunities have presented themselves to me, it may gratify you to know I have learnt (practically) both levelling and land surveying, and, as you say, "Where there's a will there's a way," I hope I may one day use them to good stead. I have tried to answer your assumption reasonably. How would the women gardeners, in whom your faith, Mr. Scot, is strengthened, relish a few stiff days' work manure wheeling or trenching, with a change to boiler cleaning and joint picking and making, all of which have fallen to the lot of—SEMPER.

A VENTURE.

WE all know there is much to be gained from the skilled pens of our superiors if we will but study them with the interest and attention they demand. I also think that there is much to be gained if we follow "Semper's" advice on the kitchen garden in the issue of April 28th. My experience is that many young gardeners do neglect this most important department. Some have thought it of no consequence to study it, and a few, to speak plainly, regard useful outdoor work as beneath them. This a great mistake. If we wish to rise in our craft we must be practical men, and not centre all our thought and work on the glass department. The pleasure ground ought also to receive our attention when opportunity allows. There is much knowledge to be gained there on hardy flowering shrubs and plants, which, as my superior often tells me, are worthy of far more study than a number of our indoor plants. If we entered in our diaries the times of sowing, planting, flowering, and using different plants and crops, we could not fail to benefit by so doing in the end. I would advise all beginners who are "roughing it," as I did for three years, in the outside department, to try and appreciate the privilege of gaining experience in the foundation work of gardening.—MULTUM IN PARVO.

[Our correspondent has acted in accordance with his signature in crowding his writing into as little space as possible. He must do the reverse if he ventures again, and write on every alternate line of his foolscap, or the end of his efforts must of necessity be the W.P.B.]

A GOOD SINGER.

I HAVE little time for writing, but I cannot let "Young Scot's" contribution on page 488 pass entirely unnoticed. He has let us know two things—(1) That he does not lack modesty, and (2) That he is a good singer in praise of himself and his countrymen. I should like to inform him that the reputation of "Scotch gardeners being the best in world" is a thing of the past, and I do so without casting the slightest reproach on the many able men among them who are not given to boasting. I con-

sider a gardener must be able to produce and show on his employer's table:—First, good vegetables and salads; secondly, good fruit; and last but not least, he must be able to arrange gracefully and artistically cut flowers where and for whatever purpose they may be required. I think it is a fact that many Scotch gardeners send South for inside foremen, as being better trained in plant growing and decoration than their own young men, who are mostly brought up to outside work.—G. H.

[If the facts are as stated by "G. H." they must be regarded as showing in a practical way the intelligence and broadmindedness of Scottish gardeners. They have high ideals, and why should not they employ young men from the South as well as southern gardeners employ helpers from the North? Among the very best gardeners of our acquaintance are English, Irish, Scotch, and Welsh, who are not given to vain boasting. A "Young Scot" is answered, and discussion on the useless subject of estimating gardeners on geographical principles ended.]

FRUIT FORCING.

Peaches and Nectarines.—Early Forced Trees.—The trees cleared of their crops must now have plenty of air, ventilating to the fullest extent, removing the roof-lights as soon after midsummer as the wood becomes sufficiently firm. If the lights are not moveable, in addition to full ventilation, the border should be frequently damped and duly watered, so that no check is given likely to induce the premature ripening of the wood and foliage.

Keep the trees free from red spider by syringing occasionally, and if necessary apply an insecticide, for the foliage must be clean and healthy to insure its ripening naturally. Laterals encourage root action, but they must be stopped so as to prevent overcrowding, otherwise some lateral extension is desirable as a safeguard against the wood and foliage maturing too early.

All shoots that have borne fruit, and which are not required for extension, should be cut away to the growths originated from their base for next year's bearing, and any superfluous wood removed, alike to make space for growths which are left, and to allow of the free admission of light and air, also for the free action of water to cleanse the foliage from insect pests and dust.

Houses with the Fruit Ripening.—The trees started early in February have the fruit advanced for ripening, and when this commences the fruit must be kept dry. With a view to prolonging the season of fruit, fire heat may be discontinued, unless the weather be unusually cold, as it has been lately, admitting air freely by day and night.

Maintain genial but not excessive moisture at the roots to compensate for the lessened amount in the atmosphere consequent on the fruit ripening. Where it is not wished to retard the fruit, maintain a night temperature of 60° to 65°, and 70° to 75° by day. Free ventilation will enable the crop to swell freely and develop good flavoured fruit, allowing a rise of 10° to 15° from sun heat.

Keep water from the fruit, but the floors and borders should be damped, so as to afford a certain amount of moisture for the benefit of the foliage. Water at the roots must be supplied to both the inside and outside border as required, and a light mulching of rather short lumpy material will lessen the necessity for it, and encourage surface roots.

Trees Swelling the Fruit.—In houses that were started in March, or where the fruit is taking the last swelling after stoning, syringe vigorously to keep down red spider. Merely wetting the trees is no use, as it does not dislodge the pest, so that the mites remain and increase amazingly after the syringing is discontinued; this seriously impairs the quality of the fruit and disastrously affects the foliage, causing it to fall prematurely, whilst the buds for future bearing are impaired.

If the trees need support supply liquid manure, or water through a mulching of short manure, sprinkling a handful of fertilisers to a square yard before watering. Admit air early and freely with the rising temperature, and to insure the fruit swelling to a large size close early with abundance of atmospheric moisture, allowing the heat to rise to 85° or 90° or more afterwards.

Turn the fruit with its apex to the light, and draw the leaves aside or shorten them, so as to admit light and air to the fruit and thereby secure its even colouring and ripening. Keep the shoots well but not too tightly tied down, and pinch the laterals back to the lowest leaf, thinning out the growths where crowded, and remove superfluous shoots.

Gathering Peaches.—Great care is necessary in removing the fruit. The least pressure makes a mark and spoils its appearance. A piece of wadding should be held in the hand and the fruit removed by gentle pressure, then laid carefully in a padded basket.

The fruit intended for packing should be gathered before it is dead ripe, a matter requiring some judgment. If gathered too soon the fruit shrivels and has a sour or insipid flavour; therefore it must be full-sized and coloured with the ripening tint to about half the extent of the fruit, then it will be in prime condition in from twenty-four to forty-eight hours after picking.

Dead ripe fruits are somewhat insipid. This can be prevented by gathering as soon as they part freely from the trees. Allowing the fruit to fall is a bad practice, but it is a good plan to fix some netting a short distance from the trees and loop it to form pockets, so preventing the fruits that do fall damaging each other by contact. Morning is the best time to gather the fruit, and it should be placed in a room to cool and mature before being sent to table. In bright weather the trees should be looked over in the evening as well as in the morning for the removal of the ripe fruit.

Late Houses.—The fruit where crowded must be thinned to the number required for the crop, or a few more may be left than will be needed to allow for casualties in stoning. Syringe morning and afternoon in fine weather, but avoid syringing on dull days, and on mornings when moisture has been condensed and hangs on the leaf margins of vigorous trees. Admit air early and freely.

Mulch inside and outside borders with short manure, and supply water abundantly. Shoots not required for next year's crop, and those not needed for furnishing the trees, should be removed. Keep all laterals closely pinched, and cut away gross shoots. The shoots on young trees should be left about 15 inches apart for bearing next year, and if they are disposed to elongate beyond 18 inches they may be pinched to 12 or 15 inches, stopping the laterals at the first leaf, but extensions or main shoots should be allowed to grow their full length, provided they are evenly balanced and there is room. Avoid laying in the growths too closely. The branches should be a foot apart, and as evenly balanced as possible.

THE KITCHEN GARDEN.

Asparagus.—Not much Asparagus should be cut after the middle of June, and cutting ought to be wholly discontinued directly Peas become plentiful. Unless strong top growth is formed and taken good care of this summer, abundance of stout, succulent shoots will not be forthcoming next spring. If mulched during the winter with manure, and this allowed to remain on the beds, the soil ought to keep sufficiently moist all through the summer. Where the beds were not so mulched, they are liable to become injuriously dry, also heavier soils to crack. This should be prevented by mulching with strawy manure before top growth is too far advanced. A watering with liquid manure or a surfacing of salt washed in by water would be of great assistance now to exhausted beds. Keep down weeds, and thin out freely any small clustering shoots of Asparagus, as these give rise to straw-like produce for cutting next season.

Young Asparagus Plants.—In good, well-established beds the growths support and screen each other; but where they are thin, as on new beds, they are liable to be broken down by wind and rain directly they become top-heavy. Preserve them with the aid of branching Pea sticks, or in a neater manner by means of stakes and strips of raffia. They pay well for this treatment. Hoe among the rows occasionally, and mulch with littery manure, where it can be afforded. Seedlings, when large enough to handle, should be thinned out rather freely, and they will then attain to a good size this season. The thinnings, if wanted, may be pricked out in fresh lines during a showery time. During wet weather slugs do much harm to Asparagus, skinning the stems. They may be checked by frequent applications of soot and lime.

Beans.—Where the more delicately flavoured Kidney Beans are preferred to Scarlet Runners, seed of the Canadian Wonder, Negro Long-pod, or other favoured variety should be sown every fortnight or three weeks, as the plants are not continuous bearing, and the pods soon become tough. The climbing Kidney Beans are more continuous, and another sowing of these, affording the plants ample room to develop, may suffice. Runner Beans are also liable to fail early in hot and dry positions. This difficulty is partly met by watering heavily, also mulching, and by sowing more seed now.

Thinning.—Crowded rows of either dwarf or running Beans are the least profitable, and the first to fail. Thin out freely the early dwarf varieties to 6 inches apart, and the stronger, later varieties to 8 or 10 inches in the row. If extra fine pods are required, thin to 12 inches apart, and support the plants with a stake to each. Runner Beans may well be thinned to 12 inches apart. One strong plant to each stake will produce more pods than two or three plants which crowd and weaken each other. Brace the tall stakes together near the top, the wind doing the least injury to rows thus strengthened.

Topping.—Stakes may be of any desired length. If not more than 4 feet out of the ground top the running growths at that height. Runner Beans to be grown without stakes must not be permitted to form any running growth. They should be kept closely topped, and abundance of strong flower spikes will then be produced from the thickened stocky stems. Mulch the rows with litter, this answering the double purpose of conserving moisture in the ground and keeping the pods clean.

Borecole, Broccoli, Brussels Sprouts, etc.—Dry weather ought not to greatly interfere with the work of cropping the ground with green winter vegetables. Left standing in the seed bed or nursery bed the plants are liable to spoil each other before rain comes. On heavy soils, or where slugs abound, the planting is best done in dry weather. Well moisten both the seed or nursery beds and planting sites an hour or two before moving the plants, and the work can then be carried out without a severe check being given. Fix the plants firmly, water copiously, and apply more as often as is required. Plants drawn from seed beds may have their roots well covered with a puddle of clay, lime, soot, and water, with advantage. Thus treated they do not flag so much after planting, and are less liable to clubbing at the roots.

Peas.—Late and much appreciated dishes of tender Peas are more surely produced by tall or vigorous growing varieties of the Ne Plus Ultra type, sown about the middle of June, than by either second early or other weakly growers, which are sometimes recommended to be sown now. Mildew is the greatest enemy to late Peas, and Ne Plus Ultra resists this disease remarkably well. Sow on deeply dug, well-manured ground, thinly, in wide drills, and cover with not less than 3 inches of soil. The seed would germinate more strongly and evenly if the drills were moistened before sowing the seed, covering with fine drier soil. Mulch the ground about the rows early.

Tomatoes under Glass.—Where only a few plants are grown, disease, notably Cladosporium, is less likely to be troublesome than where many are cultivated in houses by themselves. A warm moisture-laden atmosphere is most favourable to the propagation of this much-to-be-dreaded disease. This can only be prevented by ventilating early and never wholly closing the houses, a gentle heat in the hot-water pipes further aiding in maintaining the desirable circulation of dry air. A strong sulphurous heat with a dry atmosphere will kill the disease germs. Make the sulphur-coated pipes hot on a bright sunny day, and admit enough top air to prevent burning.

Plants already furnished with two or three lower clusters of fruit are liable to fail to set fruit on the later bunches of flowers during hot weather, apparently owing to exhaustion. They should receive abundance of water and liquid manure, and if this does not have the desired effect, very lightly spraying the roof with thin lime water will probably check the premature dropping of flowers. Topping weakly leaders will also be an aid to setting. Where young plants are growing somewhat close together remove those portions of the leaves which overhang or shade the flowers or swelling fruit, but avoid wholesale defoliation. Cutting away the greater portion of the leaves is a senseless but too common proceeding. It has a paralysing effect upon the root growth and the fruit, with the result that the fruit is defective in size and poor in quality.

THE BEE-KEEPER.

WEATHER AND HONEY PRODUCTION.

THE sudden rise in the temperature on the 8th inst., when the thermometer in the shade registered 76°, was beneficial to the bees and as this warm wave of heat continued over the three following days a great improvement was observed in all the stocks. It is several years since such perfect bee weather has been observed in this district during the first fortnight of June, and what a wealth of flowers there are in all directions. The honey-producing flowers, too, are in profusion. The Hawthorns were still a mass of bloom, on which the bees delight to work. A quantity of honey obtained from this source was stored during that time. The strong perfume arising from it was perceptible at some distance from the hives. The honey is not of high grade, being somewhat strong in flavour and not of good colour.

Field Beans, of which there are more than usual being grown this season, are now in perfection, and it is not often they are seen of such robust growth as at the present time. It is well known to all bee-keepers who study the habits of their bees how partial they are to the common field Beans, and how they will ignore almost all other flowers that may be in bloom at that time in their favour. The honey too is of exquisite flavour, preferred by some epicures to that obtained from White Clover. It has a somewhat strong aroma, though the honey does not crystallise as quickly as that obtained from some other flowers. It is brown in colour, and for that reason does not find such a ready sale amongst the general public as do the lighter samples; but anyone who has once tested this honey will not be slow to discover its good qualities.

From the above it will be seen how promising the honey prospects are, although dull weather has again set in; the barometer is high, but as the wind is in the east very little honey will be obtained until there is another change in the weather. Perhaps before many hours this may take place, but in the meantime there will be an increase of thousands of young bees daily, which will in due course be prepared to take their part in storing a surplus.

PREVENTION OF SWARMING.

One of the most important, and to some bee-keepers the most difficult, part of bee-keeping is the prevention of swarming. When bees are kept in straw skeps, and the swarms are placed in the same receptacles, it is usual for the bee-keeper to speak of his success or failure according to the number of swarms he has had. But with the bees in the modern frame hive, where they are perfectly under control, if managed on rational lines, they are prevented from swarming as much as possible, and thus a much greater surplus is stored than would be the case if they were allowed to swarm at will.

What is more annoying to the bee-keeper when a spell of fine weather sets in, and honey is abundant, to find his bees will not

work because they are influenced by the swarming mania? They may be returned to the parent hive after all the queen cells have been cut out, but on the first favourable opportunity they will swarm again to the discomfiture of the bee-keeper. When bees are in this state but little honey will be stored, and as much valuable time will be lost in manipulating them it is better to place the swarm in a separate hive and treat the original stock as occasion may require, either by raising young queens or cutting out all queen cells but one. If the former is decided on it places numerous young queens within reach of the bee-keeper which has been matured in a strong colony.

That swarming may be prevented we have proved on many occasions. During the spell of hot weather mentioned above, when stray swarms were heard of in all directions, not a single swarm came off in our apiary numbering nearly forty colonies.

SYSTEM IN BEE-KEEPING.

We leave nothing to chance in bee management, but make arrangements beforehand as to the treatment of the various stocks, and if possible keep a few days in advance of the bees' requirements. It is not at all a difficult matter when their needs are properly understood.

The three chief points to be observed in the prevention of swarming is the increase of room when the bees require it, either by enlarging the brood nest, or by giving extra space in the supers, timely ventilation and shading. Ventilation should always be given at the bottom of the hive, not at the top, as we have often seen bee-keepers who, for the want of knowing better, have removed the roof and some of the coverings from the super in the vain hope of cooling the interior of the hive. Bees treated in this manner will often refuse to work during the middle of the day, when a high temperature prevails.

In providing bottom ventilation to hives, it is necessary to have loose floor boards, unless these have some open spaces, which are covered with corrugated zinc. We, however, prefer not to have the hive attached to the floor board. Prevention of swarming is then very much simplified. The front of the hive is wedged up as much as is deemed necessary. This will allow free entrance for the bees, and abundance of ventilation.

The hives ought to be shaded during bright days, and should the weather be dull for a few days the shading may be removed, so as to allow of a free circulation of air round the hives. The above, and timely attention to small details, will prevent swarming in a marked degree. It is only by having colonies strong that a surplus may be obtained, and the bees can only be kept in their hives when in this condition by giving them the treatment they require.—AN ENGLISH BEE-KEEPER.

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8. Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Spotted Melon Leaves (*H. D.*).—The specimens shall be carefully examined, and a reply published as early as possible.

Diseased Broccoli Leaves (*K., Dublin*).—The fungus-infested leaves are under examination by Mr. Abbey, and an article on the subject of Brassica infestation will appear in an early issue.

Apple Leaves Blackened and Shoots Killed (*W. S.*).—The black on the leaves is the early form of the scab fungus, *Fusicladium dendriticum*, and the dead points of the shoots, where there would have been Apples under ordinary circumstances, have been destroyed by some caterpillar, apparently by the lesser Apple leaf roller moth, *Teras minuta*, but the fungus has also affected some of the young shoots to an alarming extent. You may spray the trees with a solution of sulphide of potassium, 1 oz. to 3 gallons of water, or use 1 oz. to 10 gallons for syringing, doing this in the lightest possible manner with a fine-rose syringe. Repeat at intervals of about ten days twice. The caterpillars had departed, being probably in the chrysalis state. The treatment with the sulphide of potassium solution will probably act as a deterrent.

Angle of Glazed Roofs—Pipes for Heating (*Tyro*).—The angle is very little regarded by practical men. We have, as have many cultivators, obtained equally good results with the glass at an angle of 35° as with it at 45°. For the Cucumbers on a south aspect we should have the roof at an angle of 45° for winter fruit, and certainly not more than 35° for Vines. If the Cucumber houses were span-roof, and ends north and south, we should not have the angle of elevation more than 35°. The piping required is about twice as much for Cucumbers as for Vines, as the first require bottom heat, while the Vines do not. We have used 30 feet of 4-inch piping per 1000 cubic feet of air for top heat to Cucumbers, and 20 feet for Vines not required to produce ripe fruit before the end of May. These figures apply to comparatively small houses, which require in proportion more piping than larger structures. It is better to have too much than too little heating surface.

Spiders (*D. R.*).—The spiders, of which you forwarded a "nest," are not injurious to vegetation, but amongst the best friends of the gardener, by preying on the insects feeding in some form or other on his crops. The species is the so-called "garden spider" (*Epeira diademata*), which, when newly hatched from the eggs in the spring, collectively spin a small irregular mass of almost invisible lines, in the midst of which the young spiders cluster together, forming themselves into a little ball about the size of a Cherry stone. This hangs, apparently, in mid-air, and when the threads forming the nest are disturbed, in an instant the solid little ball seems to be turned for a moment into smoke, so minute are the animals, so rapid their motions, and so almost invisible the means of their dispersion. The "nest" contains 600 to 800 of the bright living atoms, and after a few seconds, if the disturbance is not repeated, the little creatures begin to subside again into a cluster, but the 6000 legs or more, and the 600 or 800 pairs of poison fangs, require some time in packing so as to become resolved into a ball again. You appear to have seen this phenomena, but at a more advanced stage, the spiders being nearly dispersing.

Morels (*T. Moss*).—What you describe as a "beehive-shaped honeycomb sort of a thing," and of which you send a sample, is a medium-sized specimen of the edible fungus *Morchella esculenta*, popularly known as the Morel. They usually grow in colonies in partially shaded places in woods, and are said to be the most plentiful where the undergrowth has been burnt on the ground. They are preferred by many persons to Mushrooms, and are cooked in the same way. They are also dried and used by cooks for flavouring. We have not known them to be cultivated. The nearest approach to what may be termed cultivation we recently observed at Chiswick. The superintendent, having a number of rotten Apples at the end of the season, had them spread on a plot of land and dug in, with the object of raising seedlings for stocks. Several of these in due time appeared, but in addition great clusters of Morels. We have seen thousands growing in woods, but never before seen a bed of Morels in a garden. It is a curious occurrence, and we shall await future developments, if any. Funguses are freaksome things. Some of the finest Mushrooms we have seen were grown, and others are growing now, by the side of a path in a London suburban garden.

Pansy Roots Diseased (*J. H.*).—We did not find the "tiny white louse," which appears to have been our old acquaintance the "running" springtail, *Lipura fimetaria*, so common on decaying vegetable matter, or damp earth containing it, throughout the year. The specimens were very dry, and the springtails soon collapse under those conditions, so that may account for our not discovering the active creature. The stems of the Pansy plants were quite dead from the base to level with the surface of the soil, and that accounts for their going off. In the dead part we found the fungus called *Pleospora herbarum*, but in the macrospore stage—namely, *Macrosporium commune*, this producing a sort of dry rot in vegetable tissues. We also found the self-same section to give, under treatment with an alcoholic solution, eelworm, *Tylenchus devastatrix*, and this we consider to be the chief cause of the failure of the plants, though the fungus may have "assisted" in the operation. Why not treat the plants with a solution of Little's soluble phenyle, 1 fluid oz. to 6½ gallons of water, applying as in an ordinary watering? The eelworms will then probably take their departure, and the solution will profit the plants. It would be advisable to keep it from the flowers and young foliage. We do not know what you can now use more advantageously, applying it to infested plants at the rate of a wineglassful to 3 gallons of water. A solution of 2 ozs. kainit and 1 oz. nitrate of soda to 3 gallons of water acts well on the eelworm, applying as in watering, but not over the flowers and young foliage. For the fungus we advise a dressing of quicklime, using at the rate of 10 stones per rod, or 10 tons per acre, in the usual manner in autumn, letting it lie on the surface a short time after slaking, and spreading before digging in. This means fresh ground for the plants, using the lime as a preventive, and also dressing the cleared ground so as to disinfect it.

Peaches Dropping (*D. H.*).—The magnificent leaves have assuredly had the sap cut off from them, and we think by the brown rot fungus, *Monilia fructigena*, though we find no trace of it on the shoots, but it was on the fruits. The trees are simply too vigorous, the soil being both too moist and too rich. We should lift the trees in the autumn, doing this very carefully, as a severe check would probably cause the wood to die back, the roots very likely being long and bare of fibres. We do not know what more you can do, unless, if any gumming appears, cut off the shoots affected and burn them. Keeping the border as dry as may be without prejudice to the foliage would be of advantage, but only lifting can prove of material benefit, mixing some lime rubbish with the compost and making this firm about the roots.

Tomatoes for Market (*A Beginner*).—There is no teaching equal to that of experience. We doubt if any grower, no matter how successful he may be, is equal to naming any variety of Tomato as the best for all other growers, and those who have had the most experience are the least likely to be so dogmatic. As a rule, medium-sized, smooth, well-coloured fruits are the most in demand and realise the highest prices. One grower mainly relies on *Chemin Rouge*, another on *Comet*, a third on *Duke of York*, a fourth on *Sutton's Abundance*, a fifth on *Frogmore Selected*, and so on, and they grow these because they give satisfaction. Most growers try several varieties, and choose such for extensive culture that succeed the best with them and their methods. It does not follow that because the smooth fruits predominate in the market, and the best of them realise top prices, that corrugated varieties do not pay for growing. We had recently an opportunity of seeing that all of these are not despised. Mr. Bide of Farnham, after trying many varieties, has settled down to his *Improved Conqueror*, because he obtains a much greater weight from the plants than he could obtain from any of the smooth fruited, this more than compensating him for the slight reduction in price over first-class smooth samples. On this point, however, he had not much cause to complain, for he had a return of 9d. per lb. for large early consignments to London in May. The earlier and heavier the crops, the more profitable they are, whether the fruits are smooth or more or less ribbed, but they should be bright and tempting in appearance.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*R. W.*).—The specimens you send are florists' varieties, obtained by crossing such hardy American species as *A. calendulacea nudiflora*, *A. speciosa*, and others of similarly rich colours. The varieties resulting from such crosses are very numerous, and many resemble each other so closely that they can only be accurately named by comparison in a large collection. If you have dealings with a nurseryman who grows these shrubs extensively he might be able to give you the names of such as you enclose. We can only say that No. 1 resembles *A. nudiflora coccinea*, and 2 *A. calendulacea*. (*Picksley*).—The flowers of the four Sun Roses are closed. They are *Helianthemums*. 1, perhaps *H. cupreum*; 2, *H. roseum*; 3, *H. stramineum*; 5, *H. angustifolium*; 4, is *Limnanthes Douglasii*; 5, *Cerastium tomentosum*. The nearly obscure name on the label is *Acalypha musaica*. (*J. T.*).—1, (*Eriogonum taraxacifolia*); 2, *Muscari comosum* var. *monstrosum*; 3, *Hemerocallis lily* (Day Lily); 4, probably a young frond of *Adiantum trapeziforme*. (*W. H.*).—1, *Viburnum plicatum*; 2, *Buxus sempervirens*.

OUR DEVON AND CORNISH NEIGHBOURS.

FOR two years we have followed the footsteps of the British dairy farmer when on his annual outing, and any remarks we have made have had more reference to dairy work proper than to general agriculture. This year we fancy fresh ground has been broken, and much of interest has been seen outside milk and butter production. Devon and Cornwall are charming counties, and present many new features. Things appear to be done on a grand scale; of course, the farms chosen for inspection were picked ones, and everything that could render the visit a charming one was done.

It is pleasant to hear of luxuriant Wheat crops with promising Barley and Oats, for in the northern latitudes the two latter are doing but badly—cold, wet weather are not conducive to rapid growth. The mowing Clovers and hay fields, too, had made a good start, and no doubt with genial heat will produce immense crops.

The dairy systems of Devon and Cornwall are unique, and to some of us may appear old-fashioned, but as the price realised is so good (above London) the makers evidently know what they are about. Who has not enjoyed clotted cream and the sweet fresh butter? This butter is produced, not by machinery, but simply by the hand, after the new milk has been scalded.

Up the river Tamer was found the farm of Mr. Coryton. A farm that produced 14,801 quarts of milk in a week must be fairly given over to dairy work, Plymouth, Devonport, and Stonehouse being the markets. The cows kept here are Shorthorns. At St. Austell's the train was left, and a drive through lovely country brought the visitors to Mr. Tremayne's estate at Heligan, where the dairy herd is formed

of the Jersey breed. The cream from this milk is about 22 per cent. A fair yield, is it not? Mr. Hosken of Hayle divides his attention between his dairy cows (Shorthorn crossed with Cornish part and half-bred Jerseys), his herd of pure Shorthorns, his Lincoln sheep, and his poultry and rabbit industry. The rabbits find their home on 300 acres of grass, their ultimate destination being Birmingham and Sheffield. Over 2000 head of poultry are kept. Six incubators are used, and Mr. Hosken has found that buff Orpingtons answer his purpose the best (these fowls are also known as Lincolnshire buffs). Our experience of them is that they arrive early at maturity, and are good layers, with healthy constitutions.

Another large farm of 925 acres was visited, the home of Mr. Vosper. 100 acres for corn, 120 roots and Potatoes, the rest pasture and forage crops. The bill for feeding stuffs is £3000 per annum, and we presume also that the malt made on the premises is of no small money value. 200 South Devon cows, thirty cart horses, 300 ewes, and large white Yorkshire pigs, with innumerable poultry form the live stock. The labour bill, too, would make some of us open our eyes on Saturday night with fifty men to pay.

The most interesting thing about the Cornish sight-seeing was the Potato culture, which we may term "first earlies." On a cliff facing the south, near Penzance, digging began during the last week of April, when the price was £20 per ton; the yield is about 3 or 4 tons per acre, but the price soon drops a few pounds. This year Cornish Potatoes were in the market before Jerseys. The highest rent appears to be £9 to £6 per acre for land in the neighbourhood of Gulvare, whereas some very early near St. Ives makes as much as £20; but in one case, as the occupier netted £110 from one acre, he would not have great cause for grumbling. After the Potatoes are dug, the land is planted with Broccoli—in one case this has been done twenty-seven years in succession.

The fruit and vegetable farm of Mr. Frank Craze, Polgrain, Lelant, is most interesting. Of 112 acres, 30 acres are planted with fruit, 60 with Broccoli, and 17 acres with early Potatoes; these are followed by transplanted Mangolds, which are pulled in October, and Radishes sown for pulling in February. That land does not lie idle long—three crops in twelve months. The June Potatoes average from 4 to 8 tons per acre. On the fruit we should like to write, but refrain; it might be trenching on another's preserves.

The carriage of new Potatoes from Penzance to London is 35s. per ton; to Liverpool or Manchester 38s., and salesmen's commission with other expenses will bring the bill up to about 50s. There is a heavy outlay for tillage, as might be expected. It is not in England we find land productive when only tickled with the hoe. A mixture of farmyard manure, seaweed, and white sand is applied at the rate of 160 small loads per acre, and to that is added 1½ ton of nitrate of soda, or possibly instead 1 ton sulphate of ammonia. The Cornish acre is a trifle larger than the usual 4 rood plot. The varieties grown are Myatt's Ashleaf and Snowdrop. The rows are only 12 inches apart, and the seed set from 6 to 8 inches asunder. Of course horse-hoeing is out of the question, and so is earthing up as we understand the process. As in the Vale of Avelon, no frost or snow visits this favoured region, or practically none.

After the Potatoes are marketed then comes the second crop of the year—Broccoli Veitch's Autumn Giant. A little hoeing prepares the land, and no more manure is requisite. The carriage of Broccoli to London is 2s. 10d. per crate, each crate weighing 1½ cwt. The old story repeats itself. Man can plough, and sow and harvest, but unless he is backed up as it were by genial warmth, his best efforts but spell failure. Before we come to the conclusion that the Cornish farmer is reaping golden harvests we should remember his rent, his tillage bills, and all his hand labour, of which the Potato crop entails an immense amount, and some of it very heavy labour. Taxes, added to a rental of £9 per acre, take a good deal of gilt off the gingerbread, and that is only the initial expense. The price of the commodity had need be good, and we expect our Cornish friends have to meet light crops as well as farmers have, who do their best in outlay and skill in more northerly counties.

WORK ON THE HOME FARM.

A fine week has helped much to hurry up the work which was rapidly getting into arrears. Weeds of all descriptions have withered quickly under the influence of sun and drying winds, and the last order of twitch has been raked up and burnt under very favourable conditions. Midseason Potatoes are ready for earthing; a few late ones planted quite at the end of April are making rapid growth and will be ready as soon as we are ready for them.

Mangolds have grown well and are very promising—in fact, more so than we have seen for a long time. They have come to the hoe very quickly, and we have to make a strong effort to keep pace with them. What with side-hoeing and then striking and singling, the Mangold crop is rather exacting as to labour at a time when work is very plentiful. Doubtless this is the reason why many farmers fight a little shy of Mangolds.

Barleys have much improved, but there was so much room for improvement that even yet the prospect is not encouraging. There is more promise of a bulky crop, but there is very great unevenness, and this is sure to tell a tale in the sample bag.

Wheats look well, and the ears will soon be visible, but there are many complaints of the Oat crop, which is repeating last year's tendency to becoming blind (locally spoken of as "segging").

Turnips have come up quickly and well, and in some parts are growing quite as fast as the grower can wish, whilst in others the fly is playing greater havoc with the young plant than the oldest inhabitant can remember. Serious damage from the fly we have found to result from three causes—bad cultivation, poverty of the soil, or niggardliness as regards seed. Fly seldom or never attacks a healthy plant—i.e., a plant properly grown in well cultivated soil in a good state of fertility; but if there is a difficulty, owing to adverse weather conditions, in attaining a good Turnip tilth, and if the farmer knows from his own experience that there is a doubt about the result, then the best thing to do is to sow more seed, so as to provide for non-germination and fly attack as well. It is more expensive in seed as well as singling, but we have never missed a Turnip crop yet (except the diamond-back moth year), thinking that 9d. per acre for extra seed is well spent as an insurance.

MAGNIFICENT WHEAT PROSPECT.—Under this heading the "American Agriculturist" estimates an area of 43,500,000 acres, a remarkable increase over last year, a splendid condition of crop, and a brilliant outlook. It goes on to say, "Of course the price of Wheat for the past year has made it a foregone conclusion that the acreage this season would be large, but the "Agriculturist" and other of its more thoughtful contemporaries warned growers of the danger of too great a rush toward Wheat. A total Wheat acreage of 43,519,000 acres is a radical disturbance of the proper balance of our annual crop distribution, and there is grave danger of such a surplus of Wheat this year as was secured in 1891. The fact that Wheat supplies the world over are small, and that foreign crops only show promise of a moderate increase over last year, may offset the apparent mistake which our own large acreage seems likely to prove." British agriculturists will hope it may be so.

OUR LETTER BOX.

Poultry (Amateur).—You are right in your interpretation. The method, we are informed, is to some extent practised in France, but we are unaware of such custom in England. Perhaps you would like to write to the Editor of "Poultry," 3, Windsor Road, Church End, Finchley, London, N. The paper only costs 1d.

Preserving Eggs (Mrs. Mason).—Mr. De-la-Bere's method, about which you inquire, has been described by that gentleman as follows:—The new method is to wrap each egg the day it is laid in a small square of newspaper, and pack these eggs side by side in a box, layer upon layer until it is full. After the lid is fastened down it must firstly be stored in a dry cool place, and secondly, be turned upside down at least three or four times a week. This simple process of turning will preserve eggs perfectly fresh for 12 or even 18 months. The following were our comments at the time:—Enveloping eggs in newspaper is not by any means a new method of preservation. We have before heard of and adopted this plan in preserving eggs for eating purposes. The newspaper, in that it excludes the passage of air through the porous shell, retards decomposition and destruction of the germ. Similarly ice is prevented from melting rapidly in hot weather by being well wrapped in newspapers. Another proof of the non-conduction of heat by paper is the fact that if a newspaper be sandwiched between two blankets on a cold night radiation of heat will be much retarded, and the sleeper kept much warmer. Such methods for the preservation of eggs as greasing with butter or immersing in a solution of lime illustrate the same principle of excluding air, but unfortunately eggs thus preserved are of no use for hatching purposes, since the chicks in order to hatch alive must have a supply of oxygen, which is impossible if the pores of the shell are choked with grease or lime. We think, however, that our correspondent attaches undue importance to constant turning, for movement is likely to damage the vitality of the germinal spot, and believe that if the turning of the eggs were omitted quite as good, if not better, results would ensue, provided the eggs were carefully wrapped in paper as soon as possible after being laid.

The Royal Nurseries, Maidstone, Kent.

GEORGE BUNYARD & CO.

Are now BOOKING ORDERS for early delivery of the very best

NEW & OLD STRAWBERRIES

For Crop, 1899, or for Forcing.

They offer the Largest Stock and the Best Plants in the Trade. CHANGE OF STOCK PAYS.

Catalogues of Strawberries and Summer Fruits Now Ready

RIVERS' FRUIT TREES, Roses, Vines, FIGS, ORANGES, AND Orchard-House Trees.

A LARGE AND SELECT STOCK ALWAYS ON VIEW.

ILLUSTRATED AND DESCRIPTIVE CATALOGUE, Post Free, 3d.

THOMAS RIVERS & SON, SAWBRIDGEWORTH, HERTS.

HEADQUARTERS FOR Japan Lilies, Cycas Revoluta Morning Glory, and all kinds of Japanese Plants, Seeds, &c., &c. Large Assortment always in Stock. Orders promptly executed. CATALOGUE POST FREE.

The Tokyo Nurseries Co., KOMAGOME, TOKYO (JAPAN). Cable Address—"Nurseries, Tokyo."

BEGONIAS.

B. R. DAVIS' Gold Medal Strain. The LARGEST and MOST SUPERB COLLECTION in the World, of DOUBLE and SINGLE TUBEROUS-ROOTED. See CATALOGUE and GUIDE BOOK FREE.

B. R. DAVIS, Begonia Specialist, &c., Yeovil Nurseries, SOMERSET.

FIFTH EDITION. Price 16/-; post free, 16/6.

THE FRUIT MANUAL.

BY ROBERT HOGG, LL.D., F.L.S.

Containing Descriptions and Synonyms of the Fruits and Fruit Trees commonly met with in the Gardens and Orchards of Great Britain, with selected lists of the Varieties most worthy of cultivation.

OFFICE: 12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

KIRK'S PATENT VINE AND FRUIT BORDER SOIL TESTER.

To ascertain compost of soil, when to give water, and withhold it. A certain cure against shanking.

Sold by all Nurserymen, or direct from Wholesale Agent—**J. CRAWFORD, 18, HIGH STREET, ALLOA, N.B.**

CARNATIONS.

CHOICE SEEDLINGS, raised from the seed of the most noted Specialists only. NOW READY for immediate planting, 3/6 doz., 25/- 100. NEW CATALOGUE, comprising the newest and best exhibition varieties in cultivation, free on application.

H. W. WEGUELIN, F.R.H.S., ST. MARY CHURCH, TORQUAY.

LONDON FERN NURSERIES,

LOUGHBOROUGH JUNCTION, LONDON, S.W.—Ferns, large and small, in variety; Aralias, Grevilleas, Cyperus, Ficus, Ericas, Palms, Dracenas, Aspidistras, Hydrangeas, Pelargoniums, Fuchsias, Marguerites, Crotons, &c. Trade, send for Wholesale List. Special List for Amateurs, send for one.—J. E. SMITH.

IMPORTANT TO MUSHROOM GROWERS.—CUTHBERT'S SPECIALITE MUSHROOM SPAWN. Always alike; most productive. Hundreds of Testimonials. Per Bushel, 5/-.—R. & G. CUTHBERT, Seed, Bulb, and Plant Merchants, Southgate, N. Established 1797.

EWING'S MILDEW COMPOSITION.—The original, certain, and safe remedy. In bottles, 1/6 and 3/-; per gallon, 12/- Sold by all Seedsmen. CORRY & CO., Ltd., LONDON.

HEATING APPARATUS.—Medals 1875 and 1881. Catalogue of Boilers, Pipes, and Fittings free. W. Jones' Treatise, "Heating by Hot Water," second edition, 216 pages, 2/6; post free, 2/10.—JONES and ATTWOOD, Stourbridge.

NOTICE.—Don't stake your Carnations till you have seen the Patent Improved Coil Stake. No tying required; stakes last a lifetime. The greatest boon ever offered to growers. Only wants seeing. 7/6 per 100; sample dozen, 1/-, carriage paid. Cash with order.—A. PORTER, Stone House, Maidstone.

DEFY THE BIRDS by Buying our Noted **ROTLESS TANNED NETTING**, as supplied to the Principal Gardeners in the Kingdom. Orders over 5/- value are sent Carriage Paid. 100 yds. by 1 yd., 3/-; 200 yds. by 1 yd., 6/-; 300 yds. by 1 yd., 9/-. Can supply any length and width. — UNIVERSAL SUPPLY ASSOCIATION, East Street Works, Reading. (Name Paper.)

COTTAGE GARDENING; being an Essay to which the Royal Horticultural Society awarded Mr. W. EGERTON HUBBARD'S Prize, February 16th, 1870. By E. W. BADGER. Third Edition. Price 3d.; post free, 3d.—JOURNAL OF HORTICULTURE OFFICE, 12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—HIRST, BROOKE & HIRST, Ltd., Leeds.

GARDEN NETTING, small mesh, keep out the smallest birds, oiled and dressed; will not rot if left out in all weathers. 105 yds. by 1 yd. wide, 3/-; by 2 yds. wide, 6/-; 105 by 3 yds. wide, 9/-, and so on to any width; carriage paid on all orders over 5/-. As supplied to the Royal Gardens. Commoner netting, 50 square yds. for 1/- I do not require Payment until you have received and approved of the Netting.—From H. J. GASSON, Garden Netting Works, Rye.

PROFITABLE FRUIT GROWING FOR COTTAGERS and SMALL HOLDERS of LAND. The Gold Medal Prize Essay. By J. WRIGHT. Written for the Worshipful Company of Fruiterers. Demy 8vo, price 1/-; free by post, 1/3.—JOURNAL OF HORTICULTURE OFFICE, 12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

GREENHOUSES from £3 5/-; VINERIES, CONSERVATORIES, FRAMES, SUMMER HOUSES, &c. Illustrated List Free. Makers to H.M. THE QUEEN and H.R.H. THE PRINCE OF WALES.

Journal of Horticulture.

THURSDAY, JUNE 30, 1898.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St. London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

IN THE GARDEN IN SUMMER.

THE garden is gay with its summer bravery. It has put off its delicate colouring of early spring and the brighter hues of the later time, and is now full of the pomp of the season. The great Pæonies are resplendent with colour; big Oriental Poppies flaunt in the summer sun, with many humbler but not less beautiful sisters of the race; Irises, in many beautiful colours, are in flower; and we echo and re-echo the words of Longfellow, and say:—

"O flower of song, bloom on, and make for ever
The world more fair and sweet."

The queenly Rose gladdens us in the border and on the wall, and Lilies fair open their milk-white or crimson flowers to delight us. There is one fly in the pot of ointment among the Lilies, and that is the old yellow *L. pyrenaicum*, whose turned-back flowers emit so strong an odour as to be far from pleasant, especially on a calm evening, when we would loiter in the garden and enjoy the beauty and fragrance of its varied occupants. Sweet Pinks strive to drown the odour of the Pyrenean Lily by their delicious perfume, and the earlier Carnations join in the contest, while the scent of the Rose—ever unique—is welcomed as we pass the bushes. There are Meadow Sweets, too, pleasant enough out of doors, but sickly when in the room, though we seek to make it more pleasant by a diffusion of the old sweet Balm and odorous Thyme.

There is much fragrance in the garden—some of it sweet and soft, and all-sufficing in itself; but some needing to be toned down by leaves and flowers less marked in their perfumes. Not altogether scentless, but not pleasantly so, are the Pyrethrums, gloriously beautiful with tasselled heads, or Daisy-like in their beauty as in the single forms; while the tall Delphiniums, which have begun to open their spikes of blue, are among our scentless flowers. Creeping, or rather clambering, over trees and trellises are honey-odoured Honey-suckles—beautiful, and sweet as beautiful. Would that we made more use of them, to the gain of our gardens in grace and in fragrance.

No. 2596.—VOL. XCVIII., OLD SERIES.

There are "Daisy-Bushes," Geraniums, Violas, Pansies, Dictamnuses, Lychnises, Asphodels; there are early Campanulas, Lupines, Marigolds, Cytisuses, Saxifrages, and Stonecrops; while the House-leeks begin to thrust up their great fleshy flower stems. Flowers graceful, flowers sweet, flowers quaint, flowers stately—all have been called into birth by the heat of midsummer days; but we cannot stay now to tell of all at length.

There is something pleasing in the diminutive attached to the names of some of our plants. "Gentianella" is familiar to the most of us, and sounds softer than the shorter "Gentian." As I look out of the window—for much-wished-for rain has come—a plant of the white Fraxinella, *Dictamnus albus*, presents itself to view. To the uninitiated it is well named, so far as its foliage is concerned, "Fraxinella," or "little Ash," but those who know it well can scarce recognise the appropriateness of the name. We used to consider the purple Fraxinella, usually known as *D. Fraxinella*, the type, but it now appears that we have been wrong, and that the white form is the type plant, and that it is to be known as *D. albus*, and the purple variety by the paradoxical term of *D. albus purpureus*. The older writers cared little for these things, and some of them knew the plant as the Bastard Dittany, a name now apparently obsolete. While the purple form is much inferior to the fine variety now known as *D. caucasicus*, the white-flowered plant is almost indispensable. It is, too, a flower which stands drought well, always provided that it is established in good, strong soil, which is really necessary if truly effective plants are desired.

The luminous vapour exhaled by the *Dictamnus* has often excited much curiosity. That it is inflammable has been doubted, and some years ago an amateur who wrote about it in one of the gardening papers thought it necessary to support his statements by appending a certificate of their truth from the provost of Auchtermuchty, a Scottish town unpronounceable by the tongue of those of southern birth. A pretty plant is *Dictamnus albus* with its long spikes of ivory-white flowers of distinct form.

In the writer's all too brief college days he was often galled by the apparently purposeless repetition and reiteration of certain simple things which, however, when examination times came on, were found of almost incalculable value. So it is in writing on flowers. There are plants of which we have to speak again and again before their worth becomes recognised. One is almost afraid to say how often the *Helianthemums* or Sun Roses have been mentioned, and now that we are in the sunny months they once more put in a claim. Many who cannot grow the *Cistuses* can grow the *Helianthemums*, and although they cannot replace the former, they can be grown on sunny rockwork or dry mounds or banks with much advantage. Fugacious though they are, they are very beautiful, and a packet of seed will produce many attractive varieties which would delight almost anyone by their flowers. Less fleeting in their beauty, if heavier-looking, are the double forms. Of these nearly all are worth securing. There are double scarlet, double orange, double yellow, double cream, double white, and one or two others of various shades. They are propagated by cuttings, and in some positions look very beautiful indeed. On one rockery the writer has a patch of the double scarlet *Helianthemum*, which was planted beside the single white *Rosa pyrenaica*. The latter, as is its wont, disdains being confined to an allotted space and rambles among the stones, with the result that the scarlet flowers of the Sun Rose mingle prettily with the leaves and blooms of the Pyrenean Rose, making a charming combination.

There is a dainty little Pink in this garden of which I thought of writing a year ago. My plant was but small, and I delayed until it had attained its true character. Recently I saw a fine plant at Glasnevin Royal Botanical Gardens, and one feels that so unpretending a flower deserves some commendation. It must be premised that the name, *Dianthus suavis*, is applied by one or two of my books to a Pink which differs in some respects from that grown at Glasnevin, and here by the name. The Pink of which I speak has small white flowers, fragrant, and produced singly on rather long

stems. The foliage is small, dense, and grass-like in its general appearance. On rockwork a good plant looks as if it had hanging from it a number of silver spangles, when viewed from a little distance. It is a dainty single-flowered Pink, which should be sought after for the rock garden.

The time of summer shows has come, and pressure on the Journal's space is correspondingly great. Close one must with regretful looks at the sweet and beautiful flowers around.—S. ARNOTT.

DEFOLIATING TOMATOES.

THIS is a matter which has been much discussed, and about it there seem to be many conflicting opinions. At one time it was the usual custom to shorten back the majority of the main leaves in a rather reckless manner. This led some prominent writers to attack the practice mercilessly, and to declare that it was a barbarous proceeding to shorten the leaves of Tomatoes, and, moreover, totally at variance with all scientific teaching. Such bold assertions made the timid ones waver, and although they might be convinced by their own practice that a certain amount of leaf-shortening was advantageous, few ventured to express their opinions in the horticultural press. At the present time the matter stands in this unsatisfactory condition—that, though the majority of writers condemn the shortening of Tomato leaves, I suspect that nearly all of them practise it in some degree.

It is one of those matters which ought to be modified according to circumstances. What may be the best practice in one instance may be quite unsuited to another set of conditions. If I wanted to grow some extra large fruit of the Perfection type for exhibition purposes, I should set the plants 2 feet apart, remove all side shoots, and not shorten a single leaf; there is then no difficulty in securing splendid fruits. For ordinary purposes, however, very large Tomatoes are not desirable either for supplying the markets or private families; medium-sized smooth fruits of such fine varieties as Frogmore Prolific, Ham Green, and Challenger are invariably preferred. The point the cultivator has therefore to aim at is to secure as large a crop of fruits as possible of the right size in a given space—not undersized ones, but fully grown specimens of their respective varieties, being as far as possible without spot or blemish.

The best way to accomplish this object is, according to my experience, to plant rather closely, from 13 to 15 inches apart, and slightly shorten every leaf. Fortunately the leaf of a Tomato plant is so constructed as to lend itself to material reduction without showing any injurious results when the work is performed in an intelligent manner—i.e., done piecemeal, as opposed to the practice of severely shortening a number of leaves at one time. The plan I adopt is to shorten the leaves regularly as growth is made, rather than allow them to grow luxuriantly for a time, and then have a grand "slaughtering day." From some of them I remove one joint, from others two whenever I find the growth becomes unduly crowded; and in all instances I make a point of having the flowers fully exposed, as without full exposure perfect fertilisation is not effected. As the fruit begins to ripen at the base of the plant the leaves commence turning yellow at that point; as fast as they do so I remove them, to hasten the ripening of the fruit by giving full exposure.

In working on such lines I maintain that we so manipulate the plant as to secure the greatest possible weight of good fruit in a given space, and I have yet to learn that there is anything barbarous about the practice. It is simply a case of bending Nature to our will, and thus correcting some of her inequalities. In the case of a Vine or a Melon we resort to a severe stopping and thinning of the shoots, and I suspect the only reason why we do not systematically reduce the size of some of the leaves is that they have no natural points of division. By manipulating the shoots of a Vine or Melon we manage to get weighty crops of fruit, far superior to those which could be obtained without such reductions of growth. Why, then, should the practice of defoliating Tomatoes be termed by thinking men a barbarous one?—H. D.

A JAPANESE BLOOD-LEAVED MAPLE HEDGE.—Considering the many wonderfully beautiful effects to be had from the arrangements of plants unknown to the general public, it is puzzling that some of our more wealthy citizens do not interest themselves more in beautifying the surroundings of their residences. The resources are unlimited. Take the subject of this paragraph for instance. A hedge of this lovely Japanese Maple would surpass any effect ever attempted in landscape arrangement, and so simple too. The writer drew inspiration for this commendation from a view of about a dozen nursery rows of these Maples, the leaves just expanded, each extending a distance of 100 yards. Their beauty was unsurpassed, and would continue all the season.—T. M.

ODONTOGLOSSUM CRISPUM PRINCE OF WALES.

At the Drill Hall, on June 14th, Messrs. H. Low & Co. of Bush Hill Park Nurseries, Enfield, showed a superb form of *O. crispum* under the above name, and which is depicted in the woodcut, fig. 100. It is one of the finest varieties that has been shown, and the Orchid Committee showed its appreciation by according to it a first-class certificate and a silver Banksian medal. As may be seen, the shape of the flower is perfect, and all the segments are of exceptional substance. The sepals, petals, and lip are all pure white save for an occasional flush of rose that serves but to enhance the beauty of the flower. In the centre of the lip are brown blotches, the front lobe being white. The spike carried several flowers, and it cannot be doubted that this Orchid attracted as much or more attention than any other exhibit in the show.

CYCNOCHES MACULATUM.

This singular species, though introduced in 1839, is probably very rare in cultivation, and only seen occasionally. It has the characteristic growth of *C. chlorochilon*, but the flowers occur on semi-pendant racemes, and are pale yellow, with a plentiful spotting of rich crimson purple. It is not difficult to cultivate, thriving well in a substantial compost of peat fibre, loam, and sphagnum moss in equal proportions. It may be grown in either baskets or pots, these being well drained, and the crocks covered with a layer of rough moss. Water must be freely applied to the roots while growing, but syringing the plants is not to be recommended, especially at that stage when the young growth is apt to catch the water. After the leaves have fallen keep the roots quite dry until signs of movement appear in spring. During the earlier stages of the growth of the plant the leaves are very sensitive, and unless carefully shaded they are easily damaged. As they get older the foliage becomes harder, and more light may be allowed. The worst insect enemies to these *Cycnoches* is red spider and scale, both of which must be kept under, or good results will not follow. It is a native of Mexico.

AERIDES FIELDINGI.

The Fox-brush *Aërides*, as this species is popularly called, is one of the finest in the genus, the long, gracefully arching spikes of rosy blossoms being very fine, either alone or arranged with other Orchids in the flowering house. The plant itself is of fine habit, and the spikes appear from the upper joints of the stem. In a large tropical house this species may be easily grown on the central stage, the roots being potted in sphagnum moss and charcoal alone. Smaller plants do well in baskets suspended from the roof in the same house. It is a native of Northern India, introduced in 1850.

CAMAROTIS PURPUREA.

This pretty species is now very seldom met with in our Orchid houses, and many cultivators would not know it. The plant belongs to the same tribe as the *Vandas*, having scandent slender stems a yard or more in length, which bear toward the upper part racemes of pretty rosy purple flowers. I have often received it from seafaring friends who have purchased it in Calcutta; but, as may be imagined, these plants are not collected with much care, and are in consequence difficult to establish. When healthy, and at home in the Orchid house, the plant is, on the other hand, easily grown and very free-flowering, and is certainly worthy a place where a representative collection is aimed at.

The plants do best in the East Indian house, and may be grown in pots or baskets of sphagnum moss and charcoal in equal proportions. Plenty of root and atmospheric moisture is necessary while the plants are growing, while during winter only enough to keep the growth in good condition is necessary. Although sent home to this country by Gibson when collecting for the Duke of Devonshire's collection in 1837, it had long been cultivated in India.—H. R. R.

ROYAL HORTICULTURAL SOCIETY'S

EXAMINATION IN HORTICULTURE, 1898.

IN your comments on the above examination (page 497, June 16th), you state that one reason why there is not a greater increase in the number of candidates is because a "very considerable number of gardeners conceive that students in colleges and technical schools should, as such, have a separate examination." I fail to comprehend why it should be so. I take it that those gardeners who advocate a separate examination for trained students would also advocate an advanced series of questions for such candidates. If that were so the greater honour would still be due to the successful candidates.

The examination is not what may be termed competitive, therefore I cannot see any injustice to gardeners, nor any advantage in having two sets of examinations. There is no reason why gardeners who may be desirous to pass the examination should not qualify themselves by careful reading and study. Such men possess a great advantage, in so far as the details of practical work is concerned, over the young student, who may be struggling to understand the principles of theoretical and practical horticulture.

Possibly if the questions were confined to the practical division more

FIG. 100.—ODONTOGLOSSUM CRISPUM PRINCE OF WALES.

gardeners would enter for the examination, but I consider it would be a great misfortune to dispense with the elementary questions, as it is in these subjects that the majority of young gardeners are deficient in knowledge. Many instances could be quoted in which gardeners have strong objections to elementary principles, and absolutely decline to entertain their consideration. I have recently had experience of young gardeners declining to attend lectures dealing with the physiology of plant life, and the only excuse they had to offer was the difficulty to understand the "hard" names.

Again, I fail to understand why any person should object to these examinations on the ground that they have a tendency to "manufacture gardeners by artificial processes." In the first place it may be admitted that the fact that a person being able to give correct answers to a series of questions does not constitute a gardener, but it will generally be admitted—all other matters being equal—that anyone who possesses a knowledge of the functions of the various organs of the plants, their food, and of what is beneficial or detrimental to their healthy development, is surely better qualified to hold a responsible position than one who has no such knowledge.

The thanks of the gardening community are due to the Royal Horticultural Society for the efforts put forth to improve the education of gardeners, and to raise their status. There is a considerable amount of ambition amongst students to obtain a first-class certificate from the recognised highest authority on horticultural matters, and I trust the

Council will continue to hold their examinations, and thereby give encouragement to deserving and persevering young men to acquire as full a knowledge as possible of the occupation to which they intend to devote their lives.—W. NEILD, *Holmes Chapel*.

[If our correspondent thinks the *Journal of Horticulture* has the remotest objection to these examinations he makes a very great mistake. The Secretary of the R.H.S. could, if he liked, tell him quite a different story, but it is not in the least necessary. At the same time it is in the province of the *Journal* to register differing opinions on this or any other subject in which its readers are interested, and this will be done so long as they are appropriately expressed, as in the above communication, by an esteemed and able coadjutor.]

DISEASED BROCCOLI.

THE specimen from "K., *Dublin*," has a very singular appearance—Leaf stout and leathery, midribs yellowish, veins more so, with yellowish-white patches on the surface, and blackish spots here and there on the golden groundwork, the whole set off by a broad, more or less erumpent, white or silvery margin, very conspicuous from the contrast of the latter with the purplish-green parts of the leaf, which were the only normal portions.

The yellow and the black were determined as a peculiar form of the so-called "clubbing" (of Cabbages, &c.), and "finger-and-toe" (of Turnips) slime fungus, *Plasmodiophora brassicae*, and the white as the characteristic type of the white-rust disease of Cabbages and many cruciferous plants, the fungus named *Cystopus candidus*. There were, however, no outgrowths of this parasite, but very sparingly those of the putrefactive mildew of Cabbages and Turnips, the fungus, *Peronospora parasitica*. The latter is very often associated with white-rust fungus, sometimes the one and at others, the other being in the ascendant—that is, the fertile hyphae of *Cystopus candidus* may break through the epidermis of the host-plant and produce innumerable spores (conidia), these being distributed as visible white dust when the infested plant is sharply struck by foot of man or beast. In some cases (and this under consideration represents one) the putrefactive mildew, *Peronospora parasitica*, appears first and absolutely without any concurrent outgrowths of white-rust, nor do any in such instances appear afterwards, the putrefactive mildew being entirely master of the situation, ousting the other.

These trifles are the very root of the evil, and narrow the thing down to two forms, which may be still further reduced to one, the Myxomycete or slime-fungus, as this has sprung from the soil and entered the plant by the root-system. But the parasite must not be confounded with ordinary "clubbing" or "finger-and-toe" slime-fungus, for there is no thickening of the parts, the plasmodia simply streaming through the plant cells and breaking them down, as indicated by the yellow appearance, and the "fruits" form in the black dots, being simply spores or plasmodia differentiated and enclosed by an integument. In this state (resting) it closely resembles a "bacteroid" converting free nitrogen into assimilable (by plants), and the streaming of the plasma in the tissues of the living plant so much accord in appearance as to be scarcely distinguishable from each other. Both possess Amæba-like movements, but the "bacteroides" are symbiotic or helpful to the host, and the slime-fungus parasitic (destructive to the infested plant).

This preliminary appears relevant, from the circumstance that "K., *Dublin*," alludes to the disease infesting Plums, Cherries and Peaches. The specimen to hand (of Broccoli) has an analogous connection with the disease known as browning or "brunure" in Vines, a very similar micro-organism infesting the common Alder, *Alnus glutinosa*, and its leaves often have the whitened appearance at their margins, ultimately becoming black and falling off. The organisms, however, are quite distinct, or they assume different forms according to the host. That submitted by your able correspondent appears identical with the "brunure" of the Vine, or *Plasmodiophora vitis*, or *Pseudo-cominis vitis*, *Debray*. This I have found on Pelargoniums, Orchids, Tomatoes, Vines, and Kale, the "yellow" always preceding the brown or black; and sometimes on Brassicas, not always, the putrefactive mildew (*Peronospora parasitica*) also presents itself, and may easily be mistaken for the real culprit.

I have given a brief outline of the disease as I find it in Nature, and consider that it may be referred to the *Pseudo-cominis*, being merely a variety, as found on the Broccoli examined, the other bodies being a sequence. But let no one run away with the impression that there can be no harm done by either of the other pests, for both are parasites, commonly occurring together, and also separately, as before stated. The slime fungus in this case is the cause of the yellow and the black. The parasite has come from the soil, entered the plant from without, even if it went over as a spore with the seed, and this is a main point, for no treatment can, so far as I have investigated, enter the tissues of a living plant and kill micro-organisms therein without prejudice to the host.

The cause of the attack is (1) presence of the micro-organism, and (2) favouring conditions of existence. I am not prepared to state positively, but I consider the *Pseudo-cominis* leads a free as well as parasitic mode of life, and there is hope of prevention. For this purpose there are poisons, the most commonly used being that of fresh gas lime, which I, with many others, have frequently advised for preventing the clubbing of Cabbages and other pests. I do not consider it has any

equal for killing pests infesting land, but I find it also injures the nitrifying micro-organisms, practically sterilising the land for crops for a time.

For bare land I have not, however, found gas lime particularly hurtful when had fresh from gasworks, spread evenly on the surface, and left there as many weeks as stones or tons used per rod or acre. I have used as little as 1 stone per rod, or 1 ton acre when land must be cropped soon afterwards, and from that up to 5 stones per rod, 5 tons per acre on foul land, this being a maximum amount, and thoroughly efficacious. It was left on the surface for six weeks, and then turned under. I have tried it in both fields and gardens, and never knew it fail, nor even do much harm if put on in the autumn. This I advise, but it must not be used over the roots of crops, bushes, or trees.

Gas lime is a limited substance, I therefore pass to something simpler and safer—namely, lime. The nitrifying micro-organisms like and must have lime, and I believe, though I have not proved it, potash and soda. Lime alone, best chalk, or if vegetable soil magnesian, 1 to 10 tons per acre, or 1 to 10 stones per rod, are the amounts in which I have used it, except for particular purposes, and always to the annihilation of slime fungus. Up to 5 tons as a preventive, the smaller quantity (1 ton or 1 stone every year), and then the amounts as per year between dressings. I consider the 1 ton or 1 stone essential on all but calcareous soils. By this I mean those having the limestone or chalk mixed with the surfacing soil, for some soils on those formations need liming as much as many others.

As a cure the quantity must not be less than 5 tons, better the 10 tons per acre or 10 stones per rod. Let it be freshly burned, place in convenient lumps, just slake so to cause it to fall to a fine powder, and spread whilst hot. Leave on the surface for a time, not striving to place it in contact with the pests, but let the lime go to them in a natural way. The rains will come soon enough, and the lime will get down quite as fast as is desirable. It acts mainly on the organic matter in the soil, and I believe the ammonia gas plays the part of killing the micro-organisms and pests. Anyway, as the lime goes in the pests clear out, and the crops thrive well the following season. But this depends, for if put under in a caustic state it sterilises the land for a time.

Another application that I have found of great service in killing *Plasmodiophora brassicae* or *Pseudo-cominis vitis* is best chalk lime, air-slaked or freshly burned, and slaked with the smallest quantity of water to cause it to fall to a fine apparently dry powder; using when cool twenty parts of this to one part of kainit, 1 to 10 tons per acre, or 1 to 10 stones per rod. Broadcast it as soon as mixed, and leave it on the top for a time on arable land or vegetable ground before ploughing or digging under, applying in autumn. On sour grass land, orchards, and fruit plantations the rains will do the needful in washing in. But though the mixture may be used I think it better to use the lime separately, freshly burned, slaked, and put on hot, then follow with the kainit as soon as cool or not later than in a few days. Five tons of lime, and 5 cwt. of kainit per acre, or 5 stones of lime and 1 stone of kainit per rod will be required on tainted land, and double quantity on badly infested ground.—G. ABBEY.

CLEAN VERSUS DIRTY POTS.

UNDER the heading "Young Gardeners' Domain," in the *Journal* of June 2nd, page 469, "A Young Ross-shire Gardener" has something to say on the subject of "clean versus dirty pots." The remark, "clean pots are not necessary for healthy growth," which was one of the points in my lecture on fruit growing which recently appeared in your pages, is evidently more than this young gardener can swallow. He is to be commended in doing what he has done—going direct to Dr. "Journal" with his complaint. I am glad he has brought the matter up, and sorry I could not reply sooner. I have had several letters on this subject, and as there seems to be a misunderstanding as to what I meant, I am glad of this opportunity to make it clear.

First, let me say that the part of the pot I referred to is the inside only, and am not to be understood as advocating dirty and untidy habits. Although the washing and cleanliness of the outside of the pots in which plants are grown is of the first importance in private, and only a secondary consideration in market establishments, still, in the latter, where we find men—often young men—with considerable latitude in the management of the plants under their charge, make cleanliness and order a first consideration, we generally find the plants doing well, and is a sure indication of a good workman.

Your correspondent conjures up the shade of his dear old master. It is not so much these dear old shades I wish to be at, as those younger men of the present generation, who possess so many advantages for keeping themselves abreast of the times in all things pertaining to their calling, but who persist in following a blind rule-of-thumb practice, for no other reason than "that is how it was done when I served my time." I, too, have served under some of these "old shades," and was brought up in the full belief that cleanliness inside the pot was essential to the proper growth of the plant.

Nor do I ever remember hearing, or seeing anything written to the contrary, until I had been about fifteen years at the profession. Then I went to a place—the largest and best I had been in—where no pots were washed before use. I thought it rather queer practice at first, but when I saw the plants thrive as well as any I had seen, I could not help deploring the wasted time and money annually spent all over the country, and I resolved when I had a charge of my own I should certainly follow

out this practice, which I have now done for several years, with the best results.

A "Young Boy," June 16th, page 508, very nicely dispels the apparent inconsistency your Ross-shire correspondent sees in the practice I advocate, and my advice to young men to be thorough in all they do and have an ambition to excel. If a young man sees an easier and a cheaper way than what he now practises to gain a given end, and does not adopt it, there is little hope of his excelling in this or any other calling.

This is a matter that any in doubt can test for themselves, and I trust that the next batch of plants "Young Ross-shire" has to pot he will use one half clean pots and the other half unwashed, and give a description of the difference in the plants, if any, at the end of, say, six months. I should not be surprised if the *Cineraria* plant which stuck a little to the side of the pot with him lately is the best in the batch now.

Breaking a few roots off a plant, which to many is still such a momentous and serious affair, affords a good pretext for me to enlarge on some of the queer notions still held by many "old shades," as judged by present day, up to date, methods of cultivation, but this, with the Editor's permission, I must leave for a future occasion.—D. BUCHANAN.

[We will wait patiently. "Notes on queer notions" ought to be interesting.]

ROSE SHOW FIXTURES IN 1898.

- June 30th (Thursday).—Gloucester, and Norwich.
- July 2nd (Saturday).—Crystal Palace (N.R.S.).

* Shows lasting three days. † Shows lasting two days.

—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

TWO-DAYS ROSE SHOWS.

I WAS glad to see my friend, "D., Deal's," disclaimer on page 520, though it is rather like that of the street lad who, upon being found out, cried, "Please, sir, it wasn't me, it was the other boy." The kindness and courtesy of Mr. Mawley are universally acknowledged; but, at the risk of receiving another shaft from "D., Deal's," well-furnished quiver of satire, I must say that for the N.R.S. to advertise two-days shows side by side with those of its affiliated societies is rather a strange way of displaying its disapproval of such two-days shows, and may possibly mislead others less obtuse than myself.—HENRY B. BIRON.

ROSE SHOWS.

NATIONAL ROSE SOCIETY—BATH.—JUNE 23RD.

THE southern show of the National Rose Society was held in the Sydney Gardens on the above date. Fears were entertained that many exhibitors would not be ready to compete owing to the backwardness of the blooms, and this proved to be the case. The competition in the large classes was not so keen as usual; in many cases it was simply a question of dividing the honours. This was most notable in the Hybrid Perpetual classes. In the section for Teas and Noisettes the competitors were more numerous, and the quality of the blooms excellent. The garden Roses formed one of the chief features of the show, and were greatly admired by the dense crowd which thronged in the tent during the afternoon. The Rose world was well represented by the growers, both amateur and professional, from various parts of the country, though they were not all exhibitors.

In the premier class for forty-eight blooms, distinct, Mr. B. Cant, Colchester, secured the blue ribbon by winning the Mayor's cup, value £8 8s. The exhibit was very even throughout, and contained some grand flowers. The varieties were Ulrich Brunner, Kaiserin Auguste Victoria, Magna Charta, Rubens, Annie Laxton, Corinna, La Fraicheur, Souvenir de S. A. Prince, Madame G. Luizet, Violette Bowyer, Margaret Boudet, White Lady, Niphetos, Gustave Piganeau, La France, Lady Mary Fitzwygram, S. M. Rodocanachi, Souvenir d'un Ami, John Hopper, Jean Ducher, Jean Soupert, Marchioness of Downshire, Général Jacqueminot, Cleopatra (grand), Alphonse Soupert, Hon. Edith Gifford, Fisher Holmes, Maréchal Niel, Caroline Testout, Madame Hoste, Marie Baumann, Mrs. W. J. Grant, Devoniensis, Marie Van Houtte, Catherine Mermet, Madame Delville, Baroness Rothschild, Chas. Lefebvre, Anna

Olivier, Dupuy Jamain, Souvenir d'Elise Vardon, Prince Arthur, Margaret Dickson, Madame Cusin, The Bride, Viscountess Folkestone, and Comtesse de Nadaillac. Messrs. D. Prior & Sons, Colchester, were placed second in what must have been a very close competition. Their best specimens were Souvenir de S. A. Prince, Tom Wood, Lady Mary Fitzwygram, Prince Arthur, Marchioness of Dufferin, Souvenir d'un Ami, Captain Hayward, and Madame G. Luizet.

In the class for twenty-four blooms, distinct, Mr. G. Prince, Oxford, secured first in a close competition with fresh and bright blooms of Lady Mary Fitzwygram, Souvenir de S. A. Prince, La France, Maréchal Niel, Niphetos, Marquis Litta, Medea, Cleopatra (grand), Cornelia Koch, Marquis of Duferin, Princess of Wales, Jeannie Dickson, Comtesse de Nadaillac, Viscountess Folkestone, Kaiserin Auguste Victoria, Bridesmaid, Ernest Metz, M. Furtado, La Fraicheur, The Bride, Rubens, Madame Cusin, Madame Hoste, and Lady Alice. Messrs. J. Burrell & Co., Cambridge, took the second place with very even blooms; the best were Lady Mary Fitzwygram, White Lady, Caroline Testout, Niphetos, Innocente Pirola, Madame Lambard, and Jean Ducher.

Two exhibitors contested in the class for twenty-four triplets, Messrs. D. Prior & Son proving the winners with a fine exhibit. The varieties were Mrs. Sharman Crawford, Tom Wood, Lady Mary Fitzwygram, A. K. Williams, Prince Arthur, Madame Gabriel Luizet, Madame Hoste, La Fraicheur, La France, Rubens, White Lady, Mrs. John Laing, Grace Darling, Fisher Holmes, Marie Van Houtte, Hon. Edith Gifford, Mrs. Harkness, Mrs. W. J. Grant, Souvenir de S. A. Prince, Prince Camille de Rohan, and Niphetos. Messrs. Frank Cant & Co., Colchester, were second with, among others, good blooms of Princess Beatrice, Alphonse Soupert, Emily Laxton, Niphetos, Mrs. W. J. Grant (grand), Caroline Testout, and A. K. Williams.

For twelve blooms, any Rose, except Teas or Noisettes, a stronger competition was forthcoming, Messrs. Prior & Son winning with a grand box of Lady Mary Fitzwygram; the flowers were exquisite. Mr. B. Cant was second with a very fresh box of Madame Gabriel Luizet, while Messrs. F. Cant & Co. came third with a box of very large Lady Mary Fitzwygram.

The Tea and Noisette classes were much better filled as a whole. In the class for twenty-four distinct varieties Mr. G. Prince was well to the fore with a capital exhibit. The flowers were Princess of Wales, very fine; Hon. Edith Gifford, Souvenir d'un Ami, alba rosea, Madame Cusin, Medea, Souvenir de S. A. Prince, Comtesse de Nadaillac, Niphetos, Rubens, Amazone, Cleopatra, Maréchal Niel, Souvenir d'Elise Vardon, Bridesmaid, Innocente Pirola, Maman Cochet, Madame Hoste, Catherine Mermet, Jean Ducher, Madame de Watteville, Marie Van Houtte, The Bride, and M. Furtado.

Messrs. F. Cant & Co. were second with a very good exhibit, Cleopatra, The Bride, Maman Cochet, Princess of Wales, Bridesmaid (good), Sappho, Catherine Mermet, and Golden Gate being all worthy of mention. Messrs. D. Prior & Son were third with good blooms of Souvenir de S. A. Prince, Madame Hoste, Catherine Mermet, Rubens, and Maman Cochet.

For twelve distinct flowers Messrs. J. Burrell & Co. were first with an even display. The varieties were Souvenir d'Elise Vardon, Cleopatra, Princess of Wales, Rubens, Bridesmaid, The Bride, Souvenir d'un Ami, Golden Gate, Madame Hoste, Sylph, Hon. Edith Gifford, and Luciole. Mr. John Mattock, Oxford, was second with good Comtesse de Nadaillac, Maréchal Niel, Medea, Catherine Mermet, Rubens, Madame Caroline Kuster, and Souvenir d'Elise Vardon. Messrs. G. Cooling, Bath, were third. Their best flowers were Medea, Niphetos, Madame Hoste, and Jean Ducher.

Although only two competitors faced the class for thirty-six distinct varieties of garden Roses in trusses, the exhibits were remarkably fine. Messrs. G. Cooling & Sons secured the premier position. Their huge bunches were beautifully arranged, and, judging by the crowd that surrounded the exhibit, they were greatly admired. The varieties employed were lucida plena, Cooling's Yellow Noisette, Janet's Pride, Bardou Job, Persian Yellow, W. A. Richardson, rugosa delicata, Yellow Austrian Briar, Claire Jacquier, Papa Gontier, macrantha, Blanche de Coubert, Tuscany, Papillon, Madame A. Carrière, Harrisoni, Red Provence, rugosa fimbriata, Purity, Marquis of Salisbury, Gustav Regis, Gloire de Rosamene, Blanche Moreau, Duchesse d'Anerstadt, Hebe's Lip, Morletti, Dometil Boccard, Ma Capucine, Crested Moss, Etoile de Mai, Homer, Mdle. Laurette Messimy, Beranger, Madame Eugène Resal, and Abbé Thomasson. Messrs. Paul & Son, Cheshunt, were second with a very effective display. The most noteworthy were Camoens, Blanche Moreau, W. A. Richardson (grand colour), Paul's Carmine Pillar, Gustav Regis, Royal Scarlet, and Laurette de Messimy.

Mr. Chas. Turner, Slough, received the first prize for eighteen varieties with a fine exhibit. They comprised Janet's Pride, Madame P. Ducher, Blairi No. 2, Madame Plantier, Common Moss, Madame G. Bruant, fimbriata, Cabbage Provence, Mignonette, Bardou Job, De Meaux, Gloire des Polyantha, Pomifera, Reine Olga de Wurtemberg, Rose Apples, Blanche de Coubert, Anna M. de Montravel, and W. A. Richardson. Mr. Frank Cant was a very close second with good branches of Gustav Regis, Copper Austrian Briar, and Annie of Gierstein. Mr. John Mattock third. The gold medal for three trusses of any new seedling Rose was awarded to Messrs. Alex. Dickson & Sons, Newtownards, for a new Hybrid Tea, *Bessie Brown*, a pale creamy rose, of splendid substance, almost the counterpart of Lady Mary Fitzwygram, save in colour. The same exhibitors staged a box of new Roses, exhibiting Alice Graham, Mrs. E. Mawley (grand), Daisy, Countess of Caledon, and Tom Wood. The last-named secured the silver medal for the best Hybrid Perpetual in the show.

Mr. G. Prince secured the first prize with twelve triplets, Teas or Noisettes. The varieties employed were Cleopatra, Innocente Pirola,

Souvenir d'un Ami, The Bride, M. Furtado, alba rosea, Madame Cusin, Madame Hoste, Souvenir de S. A. Prince, Comtesse de Nadaillac, Princess of Wales, and Hon. Edith Gifford. Mr. B. Cant was second with good triplets of Cleopatra, Madame Hoste, Souvenir de S. A. Prince, Souvenir d'un Ami, and Jean Ducher; Mr. D. Prior third with good blooms, which, however, lacked the colouring that was so noticeable in the other stands.

For twelve blooms, one variety, Mr. G. Prince was first with a grand box of Maréchal Niel; Mr. B. Cant second with an exhibit of Cleopatra; and Mr. D. Prior third with Souvenir de S. A. Prince.

Single Roses were very bright and attractive. Messrs. Paul & Son, Cheshunt, were placed first for a very fine display. The varieties were Paul's Royal Scarlet, a grand single Rose; Paul's Single White, Carolina, Lady Penzance, R. rugosa, Rose Bradwardine, Paul's Carmine Pillar, macrophylla, rugosa alba, pomifera, and Nutkatense. Mr. G. Cooling was second with good trusses of Cooling's Single Crimson Bedder, macrantha, and the Austrian Briars.

The competition in the amateurs' section was very similar to that in the open classes. The boxes staged were undoubtedly good, but many well known exhibitors were missing. For twelve distinct Roses, Mr. Alex. Hill Gray, Beaulieu, Bath, was first with a very strong stand of Teas, the varieties were Souvenir d'Elise Vardon, Comtesse de Nadaillac (grand), Hon. Edith Gifford, Maman Cochet, Anna Olivier, The Bride, Princess of Wales, Maréchal Niel, Catherine Mermet, Marie Van Houtte, Princess Beatrice, and Golden Gate. This exhibit also won the piece of plate presented by Messrs. G. Cooling & Sons. Rev. J. H. Pemberton, Havering-atte-Bower, Romford, was second with good blooms of Caroline Testout, Marchioness of Dufferin, Anna Olivier, and Souvenir d'un Ami. Mr. S. P. Budd, Bath, third. The last named exhibitor was first for six triplets, with excellent examples of Madame Cusin, Marie Van Houtte, Princess of Wales, and Countess of Pembroke.

The Rev. Robt. Powley, Upton, Scudamore, was placed first for twelve distinct varieties. The competition for six varieties was keenly contested, Mr. H. P. Landon, Brentwood, being placed first; Mr. L. Parry, Stinsford House, Dorchester, second.

Mr. Conway Jones, Hucclecote, Gloucester, won the Prince Memorial cup for Teas and Noisettes.

Mr. Alex. Hill Gray was placed first for eighteen distinct varieties of Teas and Noisettes with a very strong exhibit. The best varieties were Anna Olivier, Princess of Wales, Souvenir de Thérèse Levet, and Marie Van Houtte.

Miscellaneous exhibits were a great feature, Messrs. G. Cooling & Son making a fine display of garden Roses, Palms, and other decorative plants; also a splendid exhibit of Pæonies, comprising most of the popular kinds, such as Madame Calot, fulgida Artemense, Princess Galitzen, and Baron Jas. de Rothschild.

Messrs. P. Barr & Sons, King Street, Covent Garden, staged one of their well-known displays of hardy flowers, the chief features being large collections of Pæonies, Irises, Ixias, Delphiniums, and a variety of herbaceous plants.

Messrs. R. Veitch & Son, Exeter, had a very attractive exhibit, comprising rock plants, Water Lilies, and an imposing display of hardy flowering plants, the whole forming a very bright arrangement.

ROSE CONFERENCE.

The conference held by the National Rose Society in conjunction with the exhibition at Bath proved a very successful meeting in spite of the opposition of the Coldstream Guards band, which was discoursing sweet music on the lawn. Most of the prominent rosarians were present, indeed, it might be described as a meeting of experts, though the general public were fairly represented. Mr. R. B. Cater, Bath, occupied the chair, and apologised for the compulsory absence of the Mayor. After a few brief remarks he introduced Mr. F. Cooling, who was booked to read the paper on "Rose Pruning."

The essayist commenced by dividing his subject into two divisions—namely, Roses that require close or hard pruning, and those which require very little pruning in spring. In the case of pruning Hybrid Perpetuals the first year, Mr. Cooling advocated following the orthodox advice—Prune strong growing varieties to five or six eyes, while the weaker sorts should only be allowed three or four.

Referring to garden Roses, the essayist commenced by saying there was far too much pruning done to these Roses at the present time, an opinion subsequently endorsed by the other experts present. What was really required was a thinning out of the growths at the proper season, this being done as soon as flowering ceased. By removing the part that had completed its work, the plant was enabled to utilise its energies in building up the young growth for next season's flowering, and allowing the sun and air to thoroughly mature and ripen the wood. By adopting this system the young wood is vigorous yet firm. In the autumn or early spring these growths should not be shortened, or not to any great extent, but be simply bent or pegged down. The result would be wreaths of Roses throughout the entire length of the plants.

The Noisettes, and especially Maréchal Niel, should be pruned hard as soon as the flowering period was over, probably in May or June. Select a few of the best growths that quickly appear, and rub out all weakly breaks. In September or October these growths should be pinched, or pruned back a few inches, to plump up the eyes. The Bourbon Roses require moderate pruning in spring. The Austrian and Penzance Briars should not be topped at all, but thinning is necessary, especially in the latter section. The Banksians, Crimson Rambler, and Paul's Carmine Pillar Roses require little pruning. The strong shoots should be encouraged and laid in almost their full length. Mr. Cooling then alluded to the magnificent garden Roses to be seen in our cottage

gardens, which were rarely, if ever, pruned, and suggested that gardeners might take an object lesson from them.

Mr. ED. MAWLEY, the popular Secretary of the R.H.S., after complimenting Mr. Cooling on his concise paper, said he was under the impression that the mode of pruning depended on the object in view. If we required exhibition Roses we must prune hard; on the other hand, for a garden display, the less pruning the better.

The Rev. J. H. PEMBERTON doubted very much whether we really knew much about Rose pruning, for some of the best Roses he had ever exhibited were produced on bushes that were left unpruned. He then alluded to the fact that average gardeners pruned all their Roses alike, without regard to their method of flowering; as a consequence many of the Briars never bloomed at all. He thought at the present time we had far too much of the knife in our garden Roses and too little sun. He maintained the latter was far more important in the production of Roses than the pruning knife. He also thought our Hybrid Teas were cut far too much.

Mr. GRANT followed in the same strain, instancing the wild Roses. It was preferable to leave garden Roses alone, as far as pruning proper is concerned. The cardinal points were: Remove all used up wood, and leave the strongest shoots. These do not require topping in the spring. In the case of weakly growers, pruning becomes a necessity to obtain good results.

Mr. ALEX. HILL GRAY, in the course of some humorous remarks, dwelt chiefly on the pruning of the Maréchal Niel. When he first went to reside in Bath, he protected his plants of this variety with straw; but during the winter months the mice barked the whole of them, so that he had no Roses the following summer, but the plants made such a growth that he was repaid the succeeding year with a wealth of magnificent Roses. This lesson taught him to prune hard as soon as flowering is finished, a practice he now religiously follows. He finds this Rose likes a dry climate, and will not grow satisfactorily in a damp one. As an instance, he alluded to the unsatisfactory state this variety is in in the counties of Devon and Cornwall.

Mr. F. GRIFFITH, Kotagira, Nilgiris, Southern India, somewhat puzzled the meeting by asking when he should prune his Roses, seeing that he had no winter season whatever. Mr. Grant advised him to prune when the plants appeared most at rest, which he would find about two months out of each year.

Mr. LANDON, Brentwood, and Mr. CHALLIS followed with a few remarks.

Mr. COOLING replied to the various questions put to him. The meeting then accorded him a hearty vote of thanks, and a very pleasant gathering was brought to a close.

RYDE, I.W.—JUNE 23RD.

THE above Society held its annual exhibition on Thursday last in the beautiful grounds of Westmont by kind permission of General Berthon, and notwithstanding the backward season some excellent stands of fresh and bright flowers were produced. Teas were very prominent throughout the stands, and also the H.T.'s; while the H.P.'s, although generally rather undersized, were an excellent colour.

In the open class for thirty-six blooms, in not less than twenty-four varieties, Messrs. F. Cant & Co., Colchester, won the gold medal, the silver-gilt medal being taken by Mr. R. E. West, Reigate. These exhibitors took the same order in the class for twenty-four blooms, distinct, both showing well. For twelve, distinct, amateurs, Mr. R. E. West was a good first; Mr. D. Seaton, Bitterne, second. For a miscellaneous collection of garden Roses, Messrs. F. Cant & Co. were first, and Mr. G. H. Kent, gardener to Mrs. Croft Murray, Ryde, second. Mr. B. Ladhams, Shirley, won the first prize for a bouquet of Roses with a very tasteful arrangement.

Several classes were restricted to Isle of Wight growers. For twenty-four distinct varieties, Mr. J. O. Brook, Fernside, Ryde, won the silver medal, beating Mr. G. H. Kent, who was second. Mr. J. O. Brook was also first for eighteen distinct blooms. In the class for twelve distinct, Mrs. E. C. Murray was first, Mr. G. Williams, Gatcombe, second, and Mr. J. Lee White, Cowes, third. For twelve H. P.'s only, Mr. J. O. Brook was again first, and Mr. G. Williams second. Mr. J. O. Brook was also first for eighteen, six varieties, three of each. Mr. G. Honeybourn, gardener to Lady Daly, Ryde; Mr. Frank Rashly, Haven Street; Miss Carter, Ryde; and Mrs. E. C. Murray were the prizetakers in the minor classes.

For a table decorated with Roses, with any foliage, Mr. Lee White, Cowes, was first, W. A. Richardson being the chief variety employed with chaste effect; Miss K. Collyer, Ryde, was second. Baskets of Roses, ladies' sprays, gentlemen's buttonholes, and epergnes of cut flowers, as well as floral designs. All helped to add attraction and interest to the exhibition.

The collection of wild flowers was one of the best that has been seen in the Island for some time, the wet and cold spring having helped towards the development of the native Orchids, that are chiefly found on the hills. The Bee Orchis, *Ophrys apifera*, is very plentiful and fine this year; the Black-fly Orchis, *Ophrys muscifera*, was finely developed; and also the Butterfly Orchis, *Habenaria chlorantha*; as well as the Green Man and the Frog Orchis. These and the varieties of *O. maculata*, some so fine as to remind one of *O. foliosa*, formed a very interesting and attractive feature to the botanists and others interested in the native flora. Mr. B. Ladhams, Shirley Nurseries, Southampton, exhibited a fine collection of hardy herbaceous plants and border Pinks, and was awarded the certificate of merit of the Isle of Wight Horticultural Improvement Association. Mr. Butcher and Mr. Mundell, late of Moor Park, Rickmansworth, were efficient staging Superintendents; and Mr. J. Eley an obliging and energetic Hon. Sec.

WEATHER IN LONDON.—From the day on which our last issue went to press until Monday each day was showery, and notably on Friday, Saturday, and Monday rain fell in torrents. On Tuesday and Wednesday it was bright, fine, and far more seasonable.

— **WEATHER IN THE NORTH.**—Changeable as has been the weather for the fortnight preceding the 28th inst., it has on the whole been pleasant and seasonable. An occasional cold evening has occurred when the wind set into the east, but bright warm days have been frequent. Thunder has ever and again been recurring, with heavy local showers. Everywhere vegetation is luxuriant and crops promise well, though hay will be light.—B.D., *S. Perthshire*.

— **LATE CUCUMBERS.**—A few seeds may now be sown for late summer and early autumn fruiting. The plants from this sowing will be ready to place out in about a month. They do well in frames, and come in useful when early plants are exhausted. Plants in bearing must have attention in thinning exhausted growths, removing bad foliage, stopping, tying, and regulating the growths so as to have a succession of bearing wood. Add a little fresh soil to the surface of the beds from time to time, and let the atmosphere be moist all day; it is infinitely better than shading. With the roots active near the surface, induced by a light mulching of stimulating material and liquid manure once or twice a week, growth will be sustained. Syringe at closing time, and sprinkle the paths and walls in the morning and evening. Avoid too much moisture in dull weather, or the growths will be soft and the foliage liable to injury on a bright period ensuing. Close at 85° for increasing to 90°, 95°, or 100°, and only employ fire heat to prevent the temperature falling below 60° at night. Avoid overcropping, especially of young plants, and do not allow the fruits to hang too long, as these exhaust them and prevent in a great measure a good and continuous supply.—PRACTITIONER.

— **MAGNOLIA FRASERI.**—Upwards of a century ago this species was introduced from the Southern United States, but large specimens are now not often seen. It belongs to the deciduous section of the genus, and in English gardens makes a small bushy headed tree. As a foliage plant alone it is decidedly ornamental, the leaves being 10 inches in length by 4 in width, and varying in colour from bronzy green, when not fully developed, to a pretty pale green when mature, and bright brown before falling in the autumn. The flowers when young are greenish yellow, changing as they advance in age to cream. They are sweetly scented, and when fully expanded the largest measure from 8 to 9 inches across. It is seldom without flowers during the summer, but the greatest profusion are borne during May and June. At this season the effect produced by the different shades of young and more mature foliage, buds, half and fully expanded flowers, is very striking. A plant from 10 to 12 feet in height, by the same in diameter, is flowering freely in the Azalea garden at Kew.—W. D.

— **SOMETHING NEW IN FLOWER SHOWS.**—Under the above heading the "Westminster Gazette" says: "One of the happiest ideas in connection with the 'Children's Happy Evenings' is the Children's Geranium Club, which was started last year, and includes 700 youthful members, each of whom, early in spring, receives a small Geranium plant in a pot, with the object of rearing it for an exhibition to be held in the course of the summer. This exhibition is now fixed for Monday, July 11th, at Cambridge House, Camberwell, and the Duchess of Devonshire will open this unique flower show, and award the prizes to the successful young gardeners. Miss Edith Heather Bigg, the indefatigable Hon. Secretary of the Club, to whom the poor children of London owe a considerable amount of whatever 'sweetness and light' enters into their lives, has arranged with Messrs. Segar & Wills, of South Kensington, to carry out the floral decorations for this unique 'show,' and the children's home-grown Geraniums will form the fringe round such trophies of plants as supplied by the professional horticulturists. By the time the exhibition takes place the children will have had their Geraniums for nine weeks—that is to say, they have had ample time to tend and care for the plants, the best of which will receive the prize of a watch, while fifty-six other prizes will be awarded to the young gardeners who have been introduced to one of the most charming occupations in an almost ideal manner."

— **THE CUCKOO AND CATERPILLARS.**—In reply to Mr. W. C. Stone (page 480), I have seen cuckoos devour them by hundreds.—C. C. E.

— **GARDENING APPOINTMENT.**—Mr. Wm. Humphries, late of The Gardens, Knowsley Cottage, Prescott, Lancashire, has succeeded Mr. Randall as head gardener at Holme Lacy, near Hereford.

— **TO PREVENT THE SOOTY FUNGUS ON APPLES.**—There is no question, says an American authority, but Bordeaux applied at intervals of about two weeks from the middle of June until the middle of August will prove effectual. Under favourable conditions this fungus attacks most varieties of Apples and Pears, but on all it may be controlled by the use of Bordeaux mixture.

— **RUST OF STRAWBERRIES.**—The same authority states that this can be controlled somewhat by mowing the plants after picking and burning as soon as possible. This, however, is seldom completely satisfactory, and the best plan is to spray the plants three times with Bordeaux mixture, once before fruiting and twice after.

— **EAST COWES HORTICULTURAL SOCIETY.**—On Wednesday evening, the 22nd inst., Mr. G. Groves, J.P., C.C., in the chair, Mr. S. Heaton gave the second of a series of lectures, his subject being "A Collection of Vegetables." The subject was much appreciated, and resulted in a good discussion. A unanimous vote of thanks was accorded the lecturer. Mr. J. Hygate, The Briary, West Cowes, exhibited a fine seedling Petunia.

— **A NOVEL VINE SPORT.**—There is a very interesting Vine sport in one of the houses at the Tweed Vineyard. A spur on a Gros Colman Vine has for the last six years produced a growth that is as white as the paper I am writing on. It grows freely. When I saw it last week it was about 5 feet in length, with leaves nearly the normal size, and bearing a small bunch of equal whiteness. There is no other sport in the whole vineyard. The remarkable thing in connection with it is that it is always from the same spur, which does not produce a single green leaf. It is nearly half-way up a Vine that is in robust health.—DAVID THOMSON.

— **PADEREWSKI AND THE GARDENER.**—There is probably only one gardener in Britain who has had the privilege of being enraptured in his own cottage by a private performance of the world-famed pianist. The gardener thus honoured is Mr. M. Davis, Manresa Gardens, Roehampton. M. Paderewski, accompanied by the Governor of the Bank of England, recently called at Manresa to inspect the famous Vine. The distinguished visitor was both astonished and delighted, and as he is contemplating the erection of glass structures on a considerable scale, he asked many questions. He was evidently so satisfied with the advice imparted as to give Mr. Davis an opportunity to suggest that the greatest honour of which he could be the recipient would be a visit to his cottage and a trial of his daughter's piano. The invitation was accepted with alacrity, and, to quote Mr. Davis, "the result was glorious." So is the famous Vine which he raised a little more than a generation ago, and from which has been cut, during the past dozen years, considerably more than 2 tons of excellent Black Hamburg Grapes. The present year's crop is now being removed.

— **SWEET PEAS.**—We are told that a mistake made by many growers of these is in sowing too thickly. Taking this for granted, is it not a fact that sowing too early (say in February), as so many advocate, is likewise undesirable if not a mistake? I am led to this statement after a visit to Sir William Cook's gardens the other day at Wheatley Park, Doncaster, where I observed a magnificent row, 2 feet high. Mr. West, the gardener, informed me he did not sow till the second week in April, and then just under the soil, from which the plants emerge "in no time." For some reason or another he is not troubled with birds, but if there should be a thin spot in the rows he quickly fills the sides of the earthed-up rows with more seeds, and these naturally form a most desirable succession of bloom. Mr. West told me his Sweet Peas are invariably much earlier in bloom than many of his neighbours who sow two months earlier, and I may almost as well include myself, who sowed in February in my nursery, but my plants are not nearly as forward as his. Mr. West also values Duke of York culinary Pea for an early cropper.—ALBERT UPSTONE. [We have seen Sweet Peas from 4 to 5 feet high which have been flowering for some time. They were raised from seeds sown in the open ground last November, but near a wall having a southern aspect in the grounds of Farnham Castle, the historical residence of the Bishop of Winchester, to whom Mr. W. Dowding is the able gardener.]

LESSONS OF THE SEASONS.

SCREENS AND HEDGES FOR SHELTER.

AMONGST the lessons which a cold, wet, stormy May brought to us, the necessity for a provision of shelter, and a very general lack of it around gardens, orchards, and fruit plantations was certainly one of the most important. Not merely was it enforced by the scathing effect of cold blasts upon tender spring foliage, but even more by the earlier opening of blossom and the striking rapidity of growth in every sheltered nook and corner. To the provision of such shelter one has given much thought, in view of arriving at the best possible combination of efficiency with economy. Frequently in the laying out of new gardens has the excavation and removal of soil been turned to account for throwing up banks, which, planted with evergreens of free, vigorous growth, became barriers to wind more quickly than anything else, except the costly masonry of lofty walls. It is obvious that such banks may also be rendered ornamental by judicious planting.

In the preliminary survey for the garden at Hutton Castle for Lord Tweedmouth, it was found that the best site for the kitchen

FIG. 101.—MYROBALAN PLUM AS A HEDGE PLANT.

References:—1, As received from the nursery and planted last November, 2 to 3 feet in height; 2, This represents No. 1 cut down immediately after it was planted; 3, Resultant growth this spring. The plant from which this sketch was made on May 11th had eighteen shoots.

garden was visible from the courtyard of the castle. Subsequently in the design I met the difficulty by planting out the kitchen garden with a wide belt of *Pinus austriaca* and Larch, which also would afford it shelter from north-east wind, and become an effective background to a ravine whose sides were to be planted with Thorns, Mountain Ash, Silver Birch, Crabs, Prunus, Laburnum, and Maples, with a semi-wild undergrowth of Gorse, Bramble, Briars, and Honeysuckle. Mention is made of this as an example of combining utility with ornamental effect, and of the special value of the Austrian Pine for shelter, its dense habit, vigorous growth, and hardiness rendering it especially suitable for such a purpose. Objection is sometimes taken to this tree for its sombre hue, but in this instance it was bound to prove effective as a foil to the neighbouring deciduous growth, and as imparting warmth and finish to a scene that would become increasingly beautiful with development.

The Scotch Fir, with its lighter grey foliage, is a much more general favourite, and I have used it in a design for a villa garden to be planted next autumn. The house is being built in a field near a public road, which is on the north side of it. The carriage drive will be made from the road to the house through a belt of Scotch Fir and Larch, with an undergrowth of shrubs, and a border of flowering trees and shrubs in front. This belt will sweep boldly round from the north to the east side, thus giving the requisite shelter and seclusion. The matter and manner of it is so self-evident that it strikes one as being almost too simple to mention, but then there is no getting over the fact that an adequate provision of shelter is so frequently forgotten in the laying out of gardens even in the most exposed situations.

Expense has very little to do with the matter. Failing means or convenience for wall, banks, or tree belts, a hedge is possible for everyone. Hedges of hard wood are in almost universal use by nurserymen as wind screens, such hedges being grown to a height of 10 or 12 feet in about six years. I have cause, from experience, to prefer the Myrobalan Plum for this purpose, by its dense and rapid growth, and have for the last six or seven years done what I could to advocate the planting of it around gardens, allotments, and fruit plantations. Easy enough is it to give advice in such a matter, but judging from results it appears impossible to induce amateurs to apply the few cultural hints which should render success a certainty. An object lesson was wanted, and in proof of the truth of the axiom that all things come to him who waits, my opportunity came last year, when I was requested to lay out and plant a fruit plot at the Midland

Dairy Institute. I may have something to say about this and other County Council fruit plots later on; now I have to deal with the hedge.

The site of this particular plot was so bleak that I decided to enclose it with a hedge of Myrobalan Plum, as the best means of affording speedy and efficient shelter, and moreover as an object lesson for those whom it is my duty to instruct in such matters. The soil for the plot had been carefully prepared during the summer, and the hedge was planted early in November. Healthy well-rooted plants, 2 to 3 feet in height, were obtained at the rate of 40s. per 1000. They were planted in a single row a foot apart, and cut down to about 9 inches immediately after the planting, the clean stumps so left having no prominent appearance of buds.

Quite delightful was it this spring to watch the growth, bursting out thickly on every stem. The hedge now (June 9th) is quite dense with growth, most of the shoots being upwards of a foot in length and full of vigour. Special mention is made of details, because of the advice usually given to plant 6 inches apart, and also because the plants are generally left unpruned, with the most unsatisfactory result of feeble growth and a wasted first year after planting. It is intended to have this hedge 12 feet high, and I shall be glad to have the opinion of other planters as to how long it will be in reaching that height under the requisite clipping to induce a compact dense growth. I saw stout shoots quite 6 feet long on a young hedge of this Plum last year. The small illustration (fig. 101) shows the start and progress of the plants above referred to.—EDWARD LUCKHURST.

A LITTLE MIXTURE.

THERE is generally a varied bill of fare in the *Journal of Horticulture*, in the form of heavy dishes and light relieves; but I thought I would send a little mixture of my own to meet the taste of diverse palates.

CRATÆGUS PYRACANTHA LELANDI.

Generally this fine berried shrub is grown on walls, where, with all its beauty, it assumes a somewhat formal aspect. Seldom is it seen growing in bush or pyramidal form, and yet in both cases when in bloom and in berry—but, of course, in the latter condition most, because of the rich colour of its fruit—it is most attractive. In the Coombe Wood Nursery of Messrs. Jas. Veitch & Sons there is the finest bush of this shrub I have seen. It must be from 10 feet to 12 feet through each way, and a day or two since was one mass of snowy whiteness. When in November next it is covered with berries it will be a grand object. It is to be regretted that this shrub has not been planted specially to form lawn specimens, for, whether in flower or in fruit, this Thorn is indeed a beautiful object.

HEDYSARUM MUTIJUGUM.

This is a somewhat rare hardy deciduous shrub which is just now in charming bloom at Coombe Wood. The habit is bushy, yet spreading, the foliage of the Vetch order, and much resembling that of the Dianthus. The flowers are purple Pea-like, and borne on spikes 6 inches long. It is a very charming denizen of the shrubbery, but should have a forward position. Evidently it likes a small infusion of peat, mixed with ordinary loam. *Magnolia Watsoni*, the best and most sweetly perfumed of all the deciduous varieties, is blooming finely, and for a foliage tree it would be difficult to find one so hardy and having such grand leafage as has *Magnolia Fraseri*, for the leaves are some 8 to 9 inches long, and broad yet pointed. This *Magnolia* should make a splendid lawn specimen.

LECTURES AT CHISWICK.

Those who were favoured to be present at the first of a course of four lectures on various subjects related to gardening, the first of which was delivered in the great vinery, Chiswick, by the Rev. G. Henslow, on "Vegetable Physiology," must have felt a species of homeishness, remembering the many pleasant gatherings of conference form which have been held in that fine building. But the larger portion of the gathering, some sixty in number, were young, including young men from the gardens from Kew and elsewhere, and the young lady students at Kew also. Mr. W. Marshall, of the R.H.S. Council, presided. Mr. Henslow is a most lucid lecturer, and readily makes plain, in simple and non-technical phraseology, what he wishes his hearers to understand. He mentioned at the outset, that as doctors of medicine dissected the human body, that they might understand its nature and requirements, so had botanists and vegetable physiologists, as it were, dissected plants, to have complete knowledge of them. Thus the seeds were found to consist of certain elements, that to enable them to germinate or reproduce their kind needed air, warmth, and moisture. Moisture changed solid starch into a soft or pap-like compound, capable of being utilised as food by the infant plant. That in development consisted of stem, which always grew to the light, and root or radicle, which either by force of gravitation or other cause invariably struck earthwards. Warmth generated growth, light gave chlorophyll or protoplasm, which became the green colouring of the stems and leafage, and was the vital force of the plant. Plants breathed or respired, as animals did. Much more did the lecturer tell his young audience, and added interest by numerous drawings of the conformation of roots and other parts of plants. A hearty vote of thanks was accorded at the close.

LABOUR-SAVING ARTICLES.

Any gardener doubtless is pleased when he can find in machines, or other articles, anything which lightens labour, or enables work to be

accomplished with greater facility. A few days since I saw in a hay-field at Surbiton an elevator secured to the tail of a waggon. The hay lay in windrows, and as the waggon was drawn up over them the elevator came behind and gathered it up, tumbling it into the waggon, where a couple of men built it up. I was not near enough to see whether the horses trampled on the hay, but if they did, and the hay also got well tossed about, then I fear the labour saved was lost in the deterioration of the hay. But the gardener does not want to haymake his lawns, and he has found the lawn mower a valuable aid to his labours, especially that in large gardens animals can be utilised to perform much of the work of mowing. When in Messrs. Veitch & Co.'s Coombe Wood Nursery recently, I was interested to observe the use by a man of one of the Planet, jun., double-wheeled hoes, which was being worked between rows of shrubs planted about 20 inches wide. The hoes were set to cover about 15 inches width. The progress made with the implement is not continuous like that of the horse hoe, but is intermittent. The worker has to force the implement forward by giving it a sharp push, say 12 inches, then draw it back and give a fresh impulse. In soft light soil it cuts up the weeds very well, but did not seem to sufficiently disturb them to their destruction. It is my opinion that an implement, both pulled and propelled, composed of a circular barrow armed with sharp teeth, made rapidly to revolve as the implement is propelled, would do the work of clearing the weeds to the surface more thoroughly.—A. D.

and nothing more, as to whether certain sites shall remain practically valueless, or be made valuable to the owner, tenant, manual workers, and vendors of the products of their judgment and skill. An unlimited quantity of water may flow from the chalk for centuries, and riches be washed away. It has been so; but the time comes when the right man arrives on the scene, and turns the long waste of water into a source of wealth.

He may do this in various ways, including the growing of Watercress, and this then is the crop which in certain localities is profitable alike to owner and tenant—the crop that is worth the while of a *ci-devant* worker with bricks and mortar to pay £65 an acre for the site on which he has taught himself to grow it; and, what is more to the point, by growing it and other crops, such as “Hot and Cold,” Cucumbers and Mushrooms, has in the course of a very few years indeed made himself independent of landlords by becoming one himself.

In the photographic illustration (fig. 102) is the first view of Watercress culture that has appeared in the *Journal of Horticulture*. It is only a patch of 2 or 3 acres, but as it gives an output of as many thousand pounds a year, is worth mentioning; but—and here comes the point—the

FIG. 102.—MR. NEWTON'S WATERCRESS CULTURE.

WEALTH IN WATERCRESS.

ON page 495, in the issue of the *Journal of Horticulture* of June 16th, at the end of an article on “Hot and Cold,” an outdoor crop was alluded to which enabled its cultivator, that thrifty man, Mr. William Newton, to grow at a rental of £50 an acre and leave something of a profit behind it. Various comments have been made on that statement “not for publication,” which is somewhat of a pity, for some of them were peculiar and amusing. Generally it may be said that if it were possible to concentrate the purport of the observations into about three words they would stand as follows, “I don't believe it.”

That is only what might be expected in these days when so many are striving and struggling to make a living from land under a rental of 50s. an acre instead of £50. No objection whatever is raised to the incredulity. It was only natural under the circumstances. At the same time only one slight alteration can be made on the question of veracity—namely, that the rental was, and is, in very fact, more than £60 an acre, plus rates and taxes; and still the tenant “lives,” perhaps as well satisfied with the contract as is his landlord, who is a good one, and not unknown in the horticultural world. He simply knows the value of water, and as a certain supply is an integral part of his property, he does not altogether let it run to waste.

A good deal is heard from time to time about the value of irrigation in some of our Colonies. It has also its value at home when the right men turn it to the best account, as circumstances may favour, and grow the right kind of crop in the right way. It is just a question of brains,

land had been very much of a bog for time immemorial, and worth little. Noticing a continuous stream of chalk water not far from its source, and finding by the thermometer during a sharp frost in winter a temperature of 37°, it was thought this liquid warmth might be turned to account. The land was therefore secured, and now gives an annual yield of some 300 tons of sweet and profitable “Watercreases.”

Why did it lay so long idle in comparison? The man with the thermometer had not arrived. He bought the land, formed the “beds,” and is now reaping the reward of his keen observation, judgment, and skill. He is “in the picture,” but like the modest man he is, as far in the background as possible, as the central distant figure of the work he has done so well.

Let it not be supposed that in what has been stated we are at the end of the work of this genuine working man. It will be a matter of surprise to those who know him best, if within the short space of a couple of years, and he continues to enjoy the blessing of health, he does not have a return of £10,000 a year by the sale of “Watercreases,” apart from his Cucumbers, his Mushrooms, his “Hot and Cold,” and other subsidiaries, which an earnest, zealous, sensible man who loves his work with an ardency that defies failure, continues to produce.

Enough is said at present, and a little more may perchance follow when the fates favour, on the reclamation of another swamp, and transforming it from absolute worthlessness into an area of productiveness such as is not common even in these times of earnest striving to make the best of the land.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—JUNE 28TH.

THE Drill Hall on Tuesday was packed with flowers of different kinds, those from the open ground, such as Pæonies and Delphiniums, being particularly conspicuous. Orchids were in good form, as were fruit and Tomatoes.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with Messrs. J. Cheal, J. H. Veitch, W. Poupert, A. F. Barron, M. Gleeson, W. Pope, A. Dean, W. Bates, W. J. Empson, G. Wythes, H. Balderson, F. Q. Lane, G. Norman, J. Willard, R. Fife, and T. J. Saltmarsh.

Mr. M. Gleeson, gardener to A. Von André, Esq., Stanmore, exhibited eight Queen Pines, averaging 5½ lbs. each. Mr. I. Rolfe, Stanford-le-Hope, Essex, staged some boxes of Tomatoes named Rolfe's Challenge. The fruits are a good shape and colour, and the bunches large.

Messrs. Jas. Veitch & Sons exhibited an early Cherry, Guigne d'Annonay, said to be eight or ten days earlier than Early Rivers. Messrs. T. Rivers & Son, Sawbridgeworth, exhibited six fruits of a magnificent new Peach Thomas Rivers. The fruits were excellent in shape and beautifully coloured throughout; it appears to be a decided acquisition.

Mr. Jas. Hudson, gardener to Leopold de Rothschild, Esq., Acton, showed Tomatoes and Cherries. In the former section Sutton's Abundance, Peachblow, Best of All, and Dessert were the best red varieties, while Veitch's Golden Jubilee and Golden Nugget were good yellows. The Cherries were grown on a south wall, and comprised the varieties Early Rivers and Bigarreau de Schreken.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. Fraser, C. T. Druery, H. B. May, R. Dean, W. Howe, J. Hudson, J. Jennings, T. Peed, R. B. Lowe, C. E. Pearson, H. S. Leonard, J. Fraser (Kew), J. Walker, C. E. Shea, T. W. Sanders, H. J. Cutbush, E. Beckett, G. Paul, H. Turner, D. B. Crane, H. J. Jones, C. Blick, and J. W. Barr.

Mr. C. Blick, gardener to Martin Smith, Esq., Hayes, Kent, exhibited a magnificent group of Carnations, all hailing from Hayes, which well arranged with Palms, Maidenhair Ferns, and Caladiums. The most prominent varieties were The Geisha, Nautilus, Trumpeter, Margot, Jane Seymour, Cecilia, Don Carlos, Mrs. Torrens, Mrs. de Satge, Albion, Lord Welby, and Gemma. Mr. Geo. Norman, gardener to the Marquis of Salisbury, had a handsome group of Malmaison Carnations; the blooms were very fine, and the plants remarkable for their healthy appearance; they were well staged with Palms and Cordylines.

Mr. B. R. Davis, Yeovil, Somerset, sent a very attractive exhibit of Begonias, both the double and single sections being well represented. A groundwork of Maidenhair Fern added gracefulness to the group. In the double varieties Mr. Stothert, (pale lemon), R. B. Parsons (silvery pink), Venus (pure white), Miss L. Gott (pale pink), Lucania (rich rosy pink), Salmon King, and Florence Nightingale were very fine and attractive, while the single section was well to the fore with a grand selection of seedlings, comprising colours ranging from pure white to yellow, orange, salmon, red, and crimson, the whole comprising a capital display of this popular flower. Messrs. H. Cannell & Sons, Swanley, had three trained plants of the Variegated Mallow (*Lavatera arborea variegata*) on show. The plants were well grown and beautifully variegated, clearly demonstrating the fact that this plant is suitable for decorative purposes.

Messrs. Jas. Veitch & Sons, Chelsea, exhibited a pleasing arrangement of Canterbury Bells, of the cup-and-saucer section, *C. Medium calycanthema*, comprising well-grown plants of various colours, ranging from pure white to the deepest blue. The same firm also had a large exhibit of Pæonies and Delphiniums. The former were well represented by such well-known varieties as Leda, Madame Miché, Mons. Deschamps, Gloire de Douai, Whiteley, Rubens, vittata, and Pottsi superba. In the latter section Bach, P. Laird, Lucifer, Lord Chas. Beresford, Lord Balfour, and Mr. Edgar Wilde were most conspicuous. The whole group was edged with a border of *Tropæolum polyphyllum*.

Messrs. Paul & Son, Cheshunt, exhibited a choice collection of Pæonies, varied in colour and beautifully arranged. The new single Rose, Royal Scarlet, so much admired at Bath, was well represented; the colour is intense, and its freedom of flowering beyond dispute. It will be a grand addition to this popular class of Roses. Fine blooms of the Rev. Alan Cheales, a new Hybrid Perpetual, were on view; also a very artistic group of single Begonias, lightly arranged with Maidenhair Fern. The best Begonias were Lady H. Mosley, Salmon Queen, Miss A. Stewart, Earl Grosvenor, Major Bourke, Mrs. Dudley Leigh, Lady Howe, Lady Lonsdale, Seymour Lucas, and Mrs. H. Fraser. Messrs. Sutton & Sons had a meritorious display of double Petunias, beautifully fringed and in a great variety of colours; also an attractive display of their new *Gladiolus Queen of the Roses*, a very delicate blush pink, a variety that must become popular.

Messrs. R. Wallace & Co., Colchester, exhibited a good collection of Lilliums, Irises, Calochorti, Pæony albiflora striata, Ixias, and Brodiaeas. The Lilliums comprised *L. umbellatum* incomparable, *L. u. erectum*, *L. Thunbergianum* brevifolium, *L. Szovitzianum*, *L. auratum* platyphyllum, *L. a. Wittei*, and *L. a. rubro-vittatum*. Messrs. Kelway, Langport, exhibited Pæonies, Delphiniums, Gaillardias, and Eryngiums. The most notable Pæonies were Kitty Queen, Peter the Great, Chiron, Masterpiece, Cherita, Princess of Wales, and Medusa; while the Delphiniums comprised fine spikes of Alfred Henderson, Gilbert, Imperial Majesty, True Blue, King of Delphiniums, Horace, and Oceana.

Messrs. Barr & Sons, King Street, Covent Garden, staged one of their

popular displays of hardy flowers. The chief features were a collection of single and double Pæonies, Irises, *Inula glandulosa*, Delphiniums, *Heuchera sanguinea*, and Lilliums of the Thunbergianum type. Mr. F. G. Foster, Brockhampton Nurseries, Havant, had a very attractive exhibit of Sweet Peas, which were very fine both in size and colouring, interspersed with Maidenhair Ferns. The chief varieties were Maid of Honour, Prima Donna, Chancellor, Creole, Celestial, Mrs. Eckford, Countess Powis, Grisel Hamilton, Salepian, Meteor, and Splendour. Messrs. Balchin & Sons, Hassocks Nurseries, Brighton, had an exceptional exhibit in some splendidly grown plants of *Phœnocomia prolifera* Barnesi. The plants were remarkably healthy and well flowered.

Messrs. Wm. Paul & Sons, Waltham Cross, presented a fine display of Roses in pots and baskets. The standard forms grown in pots were very good. The most prominent varieties were Madame Hoste, Madame Pernet Ducher, G. Nabonnand, Niphotos, Enchantress, and Medea. The cut blooms were very fresh and in good condition. The varieties well shown were Victor Verdier, Violette Bowyer, Grace Darling, La Fraicheur, Madame P. Perny, Empress Alexandra of Russia, White Lady, Queen Mab (grand), Papa Gontier, Caroline Testout, Madame Bois, and Marie Van Houtte. Mr. H. B. May, Dyson's Lane Nurseries, Edmonton, staged an interesting collection of Adiantums in ninety species and varieties. The most notable were *A. amabile*, *A. Veitchi*, *A. fasciculatum*, *A. cuneatum* grandis, *A. farleyense*, *A. plumosum*, *A. Hemsleyanum*, and *A. speciosum*.

Mr. E. Beckett, gardener to Lord Aldenham, exhibited a very large artistic group of Palms, brightly coloured Dracænas, Crotons, and other bright foliage plants, dotted with Lilliums in variety, Carnations, Tuberoses, Odontoglossums, and Gladioli, with a groundwork of Ferns, Caladiums, Asparagus, Isolepis, and Gypsophila paniculata, the whole having a very bright and pleasing effect. Messrs. J. Peed & Sons, Norwood, staged an attractive group of Carnations, such as J. W. Christmas, Primrose Queen, Miss Measures, R. H. Measures, and Malmaisons, arranged with Kentias and *Anthericum variegatum*. Messrs. Wm. Cutbush & Son, Highgate, occupied a large space with a group of Carnations, artistically arranged with Ferns, Bamboos, Cocos Weddelliana, and other Ferns. The chief Carnations were Churchwarden, Princess of Wales, Blush Malmaisons, the new Prime Minister and Mrs. C. H. Wilson. Messrs. Geo. Jackman & Son, Woking, occupied a large table with hardy flowers. The chief features were Sweet Peas, Campanulas alba grandiflora and *C. urticæfolia plena*, Pyrethrums in variety, Delphiniums, Pinks, and a large variety of others.

In competition for the Sherwood cup, a group of annuals and biennials, Messrs. Jas. Veitch & Sons were the only competitors. The collection staged comprised splendid bunches of Stocks, Sweet Williams, Antirrhinums, Campanulas, Sweet Sultan, Sweet Peas, Schizanthus in variety (beautifully grown), Centaureas, Petunias, and Rhodanthes. In the centre of the exhibit some huge glasses filled with these flowers attracted great attention. Leopold de Rothschild, Esq., Acton, had a very interesting exhibit of nine varieties of Water Lilies, comprising such beautiful forms as *Nymphæa stellata*, *N. Ellisiana*, *N. lucida*, *N. Marliacea chrometella*, and *N. Marliacea rosea*.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, de B. Crawshay, H. M. Pollett, J. G. Fowler, H. Little, F. Sander, A. H. Smee, H. J. Chapman, W. H. Young, E. Hill, J. Jaques, W. Cobb, H. Williams, S. Courtauld, T. B. Haywood, and H. Ballantine.

Orchids from Messrs. J. Veitch & Sons, Chelsea, were of great beauty and interest. The diversity was very pleasing, while it is needless to say the quality was of the best. Amongst the most conspicuous were *Phalænopsis Ludde-violeacea*, *Cypripediums*, *Cattleyas*, *Lælias*, *Lælio-Cattleyas*, *Disas*, *Thunias*, *Oncidiums*, *Dendrobiums* and others. Messrs. H. Low and Co., Bush Hill Park, Enfield, sent a handsome group of *Cattleyas* with one or two other Orchids intermixed. Messrs. B. S. Williams & Son, Upper Holloway, staged a small but effective group of Orchids, comprised mainly of *Cattleyas*, but including a few *Cypripediums*, *Odontoglossums*, and others. Messrs. S. Mobbs & Ashton, Southgate, arranged a bright exhibit of Orchids, the plants being well flowered.

MEDALS.—The following awards were made by the Committees for the several exhibits noted above:—Fruit Committee: Silver-gilt Banksian medal to Mr. J. Hudson, and silver-gilt Knightian medal to Mr. M. Gleeson. Floral Committee: Silver-gilt Flora medal to Mr. E. Beckett; silver Flora medals to Messrs. Kelway & Son, Cutbush & Son, J. Veitch and Sons, Ltd., and G. Norman; silver-gilt Banksian medals to Messrs. C. Blick and H. B. May; silver Banksian medals to Messrs. B. R. Davis, J. Peed & Sons, R. Wallace & Co., Paul & Son, Barr & Son, J. Hudson, and W. Paul & Son; and bronze Banksian medals to Messrs. G. Jackman & Co., G. Foster, and H. Cannell & Sons. Orchid Committee: Silver Flora medals to Messrs. H. Low & Co. and J. Veitch & Sons, Ltd.; and silver Banksian medals to Messrs. B. S. Williams & Son and S. Mobbs and Ashton.

CERTIFICATES AND AWARDS OF MERIT.

Begonia Florence Nightingale (B. R. Davis).—A pure white double variety of the best quality (award of merit).

Begonia Thunderer (B. R. Davis).—This is a grand double variety, with glowing scarlet flowers (award of merit).

Campanula mirabilis (G. Jackman & Son).—A charming variety, with pale blue upright flowers, which are abundantly produced (first-class certificate).

Carnation Lord Welby (C. Blick).—A grand flower. It has size, substance, and rich red colour (award of merit).

Carnation Margot (C. Blick).—The petals of this are of great breadth and thickness. The colour is rich rose (award of merit).

Carnation Baldwin (C. Blick).—One of the grandest pink varieties. It is large and well built (award of merit).

Carnation Mrs. de Satge (C. Blick).—A good scarlet, with large good shaped flowers (award of merit).

Cattleya Adela (J. Veitch & Sons). A hybrid resulting from a cross between *C. Percivaliana* and *C. Trianae*. The sepals and petals are rich rose, with a purple suffusion, the beautiful lip being crimson paling towards the margins (award of merit).

Cypripedium P. Ansoni (H. Low & Co.).—A fine form after the style of *Rothschildianum*. The petals are cream with immense brown spots, and are slightly drooping. The dorsal sepal is creamy white with brownish crimson veins. The pouch is pale claret (first-class certificate).

Cypripedium Mrs. Reginald Young (H. Low & Co.).—This is a handsome Orchid, with long, drooping, wavy petals, the colour of which is cream with large bright claret spots at the base, and dull claret about 6 inches from the tips. The dorsal sepal is bright yellowish green and glowing crimson brown. The pouch is pale orange claret (first-class certificate).

Digitalis purpurea grandiflora (J. Veitch & Sons).—The varietal name of this Foxglove tells its colour. The flowers are of good size (award of merit).

Gaillardia W. B. Child (Kelway & Son).—This is a splendid variety with brilliant yellow flowers (award of merit).

Gladiolus Queen of the Roses (Sutton & Sons).—This is a handsome and very floriferous *Gladiolus* that should become exceedingly popular. The colour is soft rose (award of merit).

Iris Juncea humida (R. Wallace & Co.).—A lovely form. The colour is bright yellow save for occasional brown veins (award of merit).

Lælio-Cattleya Canhamiana Joyce Wigan (W. H. Young).—A superb variety. The sepals and petals are delicate rose, deepening to purplish rose towards the margins. The fine lip is purplish crimson (award of merit).

Lilium Marhan (C. G. Van Tubergen).—A handsome *Lilium*. The flowers are numerous, and of a buff colour, with numerous bright brown spots (first-class certificate).

Lupinus polyphyllus Somerset (Kelway & Son).—A fine yellow variety of the well-known type (award of merit).

Nasturtium Queen of Tom Thumbs (Watkins & Simpson).—The deep-coloured flowers and the silver variegated leafage of this variety are very effective (award of merit).

Peach Thomas Rivers (T. Rivers & Son).—An immense Peach of excellent appearance. The flush of colour extends over almost the whole surface. The flavour is very good, but the fruit tested was slightly stringy (first-class certificate).

Philadelphus Lemoinei (Barr & Son).—An extremely floriferous variety with pure white flowers (award of merit).

Rose Rev. Alan Cheales (Paul & Son).—A fine H.P., with bright red, well-formed flowers. The reverse of the petals is silvery (award of merit).

Rose Una (Paul & Son).—A grand single Rose, with large cream-coloured flowers (award of merit).

Stanhopea Rodigasiana (W. H. White).—A remarkable Orchid. The broad thick lower sepals are pale yellow, with large and numerous brown spots, the upper sepal being the same colour without the spots as are the petals. The lip and column are densely spotted with rose, the throat being white. The flower is borne on a spike some 10 inches in length (first-class certificate).

FLOWERS AND GREENERY FOR MARKET.

SOME three or four years have elapsed since I looked in upon those veteran market growers, Messrs. Hawkins & Bennett, Twickenham, whose great forte so long has been the production of Zonal Pelargonium flowers for market sale, and some other products also. So far they have been enabled to resist the grasp of the builder, but they are gradually becoming enclosed by houses, and in a few years the nursery may have to be removed elsewhere. In the meantime they go on growing Pelargoniums, Lilies of the Valley, Roses, Stephanotis, and other specialities with entire equanimity.

Very long house after house is full of plants, old and young, of Pelargoniums. The best doubles for their purpose are F. V. Raspail, and that wonderfully fine sport Duke of Fife, for which the firm obtained a "F.C.C." some six years since. Of all the sports that have come from Raspail none is finer than this one. The new salmon coloured King of Denmark is there also, but so far on trial. The ordinary white double is Cannell's Silver King, a sort of white Raspail, but holding the same relation to it as Duke of Fife does. P. Lemoine is a superb pure double white, and is highly favoured by the firm for their purposes.

The most widely grown singles are H. Jacoby, J. Gibbons, West Brighton Gem, and that rich scarlet De Lesseps. A singularly lovely rosy salmon is Lady Chesterfield, the most pleasing of that section of colour I have seen. Of ordinary pink colour Constance is the favourite, whilst of whites Aurelia, a good winter white, but colours pink when exposed to the full light in the summer, Queen of the Belgians, and a pure and steadfast seedling of their own, are most generally grown. Flowers of all these singles are fixed with a drop of gum before they are bunched for market. Some plants of Madame Crousse Ivy-leaf are grown too, but these are more in demand for boxes or baskets than for furnishing cut flowers.

LILIES OF THE VALLEY.—Now over, are very finely grown, the large Victoria form being the only one. The beds are some 7 to 8 feet wide and very long. There are large quantities of moveable backs,

fronts, and ends, that can be fixed as needed over the beds, and on them be laid lights, or in some cases stout wires are trained from end to end, and on these canvas coverings are laid to furnish protection in the spring from white frosts. The beds are lifted, broken up, and replanted every eighth year. Then the whole of the old soil is removed, and it is replaced by fresh, and the best crowns are selected and replanted some 2 or 3 inches apart all over the surface. Top-dressings of manure are liberally given in the winter, also from time to time soakings of liquid manure. The culture is indeed of the very best, and the flower product of the finest.

STEPHANOTIS FLORIBUNDA.—This has been grown in a long low house for many years. The house is about 6 feet wide, and seven wires, each 100 feet long, are filled with luxuriantly flowered wood, covering them. The plants are chiefly in large slate tubs or boxes, the sides and ends being bolted together. When, each other winter, it is needful to add fresh soil, the bolts are removed, the sides and ends taken away, a large portion of the soil is then forked off, the slate sides and ends replaced, and new soil added. In that way the plants continue from year to year to grow and bloom profusely. *Hoya carnosa*, in large pots in another house, also grows profusely, and is carrying myriads of clusters of wax-like flowers. These, too, have a value in the market, as they sparkle so in the strong artificial light now so common in places of resort.

MAIDENHAIR FERNS.—Always the popular *Adiantum cuneatum* is another strong feature. There are apparently thousands of plants in 9-inch and 10-inch pots, from which fronds that have become well hardened are constantly being gathered. Then the plants get a period of rest and come on again. Some that seem to need renovation are broken up into several pieces and placed in smaller pots. In such an industry the greatest care must be taken to have not only a constant but also an abundant supply. Maidenhair fronds keep well on the plants, so that if the demand for a time runs low there is no waste. It would, however, be a serious misfortune did a sudden demand find the firm unable to meet it.

SMILAX.—This is now grown very extensively. There are hundreds of pots of this useful climber standing on beds in the houses in cross rows. Wires are strained tightly across close on the pots, whilst others run across 4 feet above. From wire to wire lengths of twine are fixed, and up these the Smilax growths run in wonderful profusion. These lengths are cut when well furnished, and sent to market. They are produced in about three weeks. Smilax is easily raised from seed, and when old plants are exhausted fresh ones are ready to take their places.

A few varieties of *Begonia Rex* are grown—one, a bronzy leaf, and another, having pretty spotted leaves, to sell as plants for vase decoration in rooms. Roses are chiefly grown against walls, outdoors; and there is a large stock of Chrysanthemums in pots, preparing for autumn and winter blooming. Naturally in establishments of this description something or other must always be at hand to market.—A. D.

LEEDS HORTICULTURAL SHOW.

JUNE 28TH.

THE Leeds Committee is for the first time for many years to be congratulated in getting together a really good show under specially favourable climatic conditions. Last season, after a lapse of about ten years, a spirited attempt was made to resuscitate what had promised to become one of the leading shows in the North, and although a good show was the result, the weather then was far from satisfactory, and the venture a financial loss to the Committee. With characteristic determination not to be defeated at the first attempt, another effort has been made, which only requires the support of the inhabitants of Leeds to make a grand success. The show in all its features is a marked improvement on last year's venture.

The fruit classes were well filled, and in most cases the competition was close. Mr. Goodacre, gardener to the Earl of Harrington, was first with a good Melon, Apples, Strawberries Royal Sovereign, Figs Brown Turkey, Nectarines Violette Hâtive, Peach Chancellor, well finished Black Hamburg Grapes, and especially good bunches of Cannon Hall Muscat. Mr. McIndoe, gardener to Sir Jos. Pease, was second, showing good Hamburg and Muscat Grapes, and a fine Melon of the Empress type. Mr. J. Tullett, gardener to Lord Barnard, Raby Castle, was third.

For three bunches of Black Hamburg Grapes, Mr. Goodacre was again first. Mr. W. Nicholls was a good second, and Mr. A. Large, Ripley, third. For three bunches of black Grapes, any other variety, Mr. F. Nicholas, gardener to the Marquis of Zetland, was first with well finished Madresfield Court, Mr. McIndoe second, and Mr. Easter, gardener to Lord St. Oswald, Nostell Priory, both exhibiting the same variety. For two bunches of white Grapes, Mr. Nicholas won with superbly finished Buckland Sweetwater, Mr. A. Large second, and Mr. McIndoe third with Muscat of Alexandria.

For six Peaches Mr. Goodacre was first with fine examples of Noblesse; Mr. Alderman, gardener to J. P. Ellis, Esq., second. For six Nectarines Mr. Goodacre was first with superb Lord Napier; Mr. Alderman second; and Mr. Bennett, Market Drayton, third. The first prize for scarlet-fleshed Melons was won by Mr. F. Nicholas; Mr. W. Abbey second; and Mr. Goodacre third. For green-fleshed Melons Mr. McIndoe was first; Mr. Goodacre second; and Mr. W. Nicholls third. For a dish of Strawberries Mr. Alderman was first with Royal Sovereign; and Mr. Lawton, gardener, Welton House, second, with fine examples of Gunton Park.

Groups of miscellaneous plants arranged for effect in a space of

250 square feet. Four exhibitors competed, the first three being remarkably fine arrangements. Messrs. Simpson & Sons, Selby, secured first place with a well balanced and effective arrangement, Mr. Townshend was a capital second, whilst Messrs. Sharp & Co., Almondsbury, were placed third.

The lesser group of 120 square feet, for amateurs resident within seven miles of Leeds, showed good quality and taste in arrangement, Mr. Fairfax Rhodes, Potternewton House, securing first honours; second, Mr. Eastwood, gardener to Mrs. Tetley; third, Mrs. Kitchen, Eller Close, Roundhay. For six stove and greenhouse plants in bloom, Mr. F. Nicholas secured first place with *Pimelea mirabilis*, *Clerodendron Balfourianum*, *Erica Cavendishi*, *Anthurium Scherzerianum*, *Franciscea calycina major*, and *Aphelaxis rosea*. Mr. Sharp was second and Mr. J. Sunley third. For six ornamental foliage plants Mr. Nicholas was first; Messrs. Simpson & Son second; Messrs. Sharp & Co. third. For a single specimen foliage plant Mr. Townshend was first with a magnificent *Cycas revoluta*; Mr. Walker second, and Messrs. Simpson & Son third. For three Crotons Mr. Nicholas was first, Messrs. Simpson second, Messrs. Sharp third.

Roses made a remarkably fine display. Messrs. Dickson & Sons, Newtownards, were easily first for forty-eight distinct varieties. Their chief examples were Marquis Dufferin, A. K. Williams, Lady M. Fitzwygram, Mons. E. Y. Teas, Mrs. R. Sharman Crawford, Bessie Brown, La Rosière, Duke of Edinburgh, Marquis de Castellane, Tom Wood, La France, Jeannie Dickson, Madame H. Jamain, The Bride, Avoca, Muriel Graham, Mrs. W. J. Grant, Liberty, Souvenir de S. A. Prince, Niphetos, Countess of Caledon, Général Jacqueminot, and Rubens. Second, Messrs. Harkness & Son, Bedale; third, Messrs. G. and W. H. Burch, Peterborough.

For twenty-four varieties Messrs. Dickson & Son were again first, and well ahead with varieties similar to the foregoing. Messrs. Harkness second; Messrs. F. & A. May third. For twelve Tea-scented Roses Mr. Burch was first with Niphetos, and Messrs. Harkness & Son second.

For twelve bunches of stove and greenhouse flowers Mr. Nicholas was first and Mr. McIndoe second. Bouquets were superb, Messrs. Perkins and Sons showing in their usual style for first honours; Mr. A. Hall, Harrogate, was second. In the same order honours fell for exceedingly tasteful basket arrangements. Table plants, Gloxinias, exotic and hardy Ferns were fine fresh examples. The lion's share of prizes fell to Mr. Eastwood for superb examples of Pelargoniums and Fuchsias.

In the miscellaneous exhibits the enterprise of Messrs. Clibran & Sons was conspicuous by a magnificent collection of herbaceous Peonies, among which Duke and Duchess of York, finely perfumed; grandiflora rosea, Rubens, and Snowdrift stood out remarkably fine. Mr. A. Hall, florist, Harrogate, showed tasteful arrangements in wreaths and ladies' sprays; while Messrs. Webb & Son, Stourbridge, exhibited a collection of Sweet Peas, Delphiniums, Pyrethrums, Tomatoes, and Cucumber Stourbridge Gem.

URSINIA (SPHENOGYNE) SPECIOSA.

THE above is the name of "Devonian's" specimen, and we think your plants are flowering unusually early. This may be accounted for by your genial climate, for as a rule this annual blooms from July onwards. No, it is not new, for it was introduced under the name of *Sphenogyne* so far back as 1837. The woodcut (fig. 103) will convey an idea of the value of this hardy annual for border decoration. The seeds may be sown in the open ground along with the other annuals in early April; all that is required afterwards is simply thinning the seedlings to 6 or 9 inches apart, which is quite near enough, as they have a branching habit, each forming a well-shaped bush literally covered with its bright yellow flowers, the effect of which is greatly enhanced by the dark purple brown spot at the base of the rays, and the rich dark disc. The variety *sulphurea* is not so beautiful as the type, the flowers being pale sulphur. *U. anthemoides* is a near ally of the above, differing in having a deep purple colour on the under side of the rays, smaller flowers, and more finely cut foliage.

THE YOUNG GARDENERS' DOMAIN.

BUSH MIGNONETTE.

THE most useful form of training Mignonette is, I think, in the form of a bush. The seed should be sown about the middle of February in clean, small, well-drained pots, using a compost of two parts loam and one of leaf soil, with a little silver sand added. Three or four seeds suffice for each pot. Well water with a fine rose, and place in a warm pit. As soon as the plants are large enough to handle, thin them out, leaving the strongest one as near the centre as possible. In a short time they will gain strength, and when the plants have well filled the pots with roots they should be transferred to 5 and 6-inch pots, using at this stage a mixture of turfy loam, leaf soil, and well-decayed manure in about equal parts, with a free admixture of sand and small charcoal, potting rather firmly, and shading from bright sunshine. The shoots must be pinched at intervals to produce a branching habit. By the beginning of June the plants should be ready for shifting into 8 and 9-inch pots. When the

roots are working freely in the new soil the plants may be arranged on the north side of a wall. The flowers ought to be removed as they appear till about the middle of September. As the nights grow cold place them under glass in a temperature of about 55° at night. They should never be allowed to receive the slightest check, but kept continually growing, watering very carefully, and syringing in bright warm weather. —S. S.

CYCLAMEN PERSICUM.

To obtain a good supply of blooms from November to March the following is the mode of culture practised. Our main sowing is made in August in clean thoroughly drained pans filled with light leafy soil. The seed is covered lightly, and the pans placed on a hotbed about 80°. The seed germinates irregularly, and mistakes have been made by

FIG. 103.—URSINIA (SPHENOGYNE) SPECIOSA.

emptying seed pans too soon. As soon as large enough the plants are carefully placed into thumb pots and arranged on a shelf near the glass in a house having a temperature of 65° to 75°. The syringe is used on favourable occasions. Shading is attended to, and the plants given larger pots as required. More air is afforded as the season advances, and by June the plants are ready for their final shift into 5-inch pots.

The compost employed consists of peat, sweet leaf soil, and loam in equal parts, with the addition of sharp sand and crushed oyster-shells. The potting is done without the use of the rammer, and in such a way that the base of the corm rests on the surface of the soil when the work is finished. This is important in order that watering may be properly done. The plants are then arranged on ashes in cool frames, and syringed thoroughly, especially on the under sides of the leaves, until the flower buds appear. The regular syringings help to keep down that most troublesome pest of the Cyclamen, the white thrips, which attacks the crowns, and is responsible for most of the "blindness" which occurs in the plants.—T. P.

(To be continued.)

FRUIT FORCING.

Vines.—*Early Forced Houses.*—When the Grapes have been cut the Vines should be thoroughly syringed to cleanse them of dust and insect pests. The worst of these is red spider, which in its countless numbers so impoverishes the leaves that they fall prematurely, and the buds are then so ill-formed and nourished that the growths from them in the following year are weak and the fruit poor. Moderate extension of the laterals should be encouraged from the extremities only. Vines must not be allowed to go to rest prematurely, or they will make a second growth late in the summer. Ventilate to the fullest extent day and night, and if the roof-lights can be removed all the better.

Grapes Colouring.—Free circulation of rather dry warm air contributes to high flavour and finish. The temperature should be maintained at 70° to 75° by day, and 60° to 65° at night; with sun heat a temperature of 85° or 90° may be allowed. Vines struggling with a heavy crop should not be subjected to so high a temperature as those which are luxuriant and carrying no more fruit than may be considered a fair crop, but rest must be afforded them at night by allowing the temperature to fall to 60°. Afford a thorough supply of water to the border, mulching with an inch or so of short manure. Outside borders in most cases have been sufficiently moistened by the recent rains. Moderate air moisture is necessary for the foliage, damping down in the morning and afternoon, but a close atmosphere is fatal to colour and bloom, and is likely to induce "spot" in the tender-skinned white Grapes, such as Duke of Buccleuch and Muscat of Alexandria.

Late Houses.—Thinning the berries will in most cases be completed, though it may be desirable to go over the bunches again by the removal of superfluous or stoneless berries. For securing highly finished berries it is necessary to thin them well, especially in the interior of the bunches, leaving the large-berried varieties, such as Gros Colman, not less than an inch apart. Oval berries do not require quite so much room, but all must be free to swell without wedging, and yet the bunches should retain their shape when dished. An array of footstalks is not pleasing. Do not spare the bunches where there are too many, but reduce them to the number which the Vines can finish satisfactorily. Over-burdened Vines never finish their fruit well, and it will not long keep sound.

Firing and Ventilating.—When the Grapes are thinned they swell rapidly up to stoning, and then remain stationary for a month or six weeks. Cold nights render fires still necessary, and it is the reverse of economical to let them out and lose size in the Grapes, and then have to fire hard later in the season, when the sun has less power to ripen the fruit. All late Grapes require a high temperature and a long season, with abundant nutriment at the roots and a plentiful supply of atmospheric moisture. Maintain the night temperature at 60° to 65°, and 70° to 75° in the daytime artificially. Admit a little air early in the morning, but never to lower the temperature and increase it with the rising heat, which should go up to 85° or 90° from sun heat, and the longer that is kept the greater progress the Grapes make. Reduce the ventilation when the sun heat wanes, closing the house by the time it recedes to 85°, well damping the paths then, and the heat may rise to 90° or 95° afterwards with benefit. It is always desirable to make the most of sun heat, and aid it with artificial warmth. A little air at the top of the house at night will allow the vitiated atmosphere to change, and the foliage to become dry in the morning by the time the sun acts powerfully upon the structure. If care is taken to increase the ventilation with the advancing sun scorching will be avoided.

Watering.—The warm rains of summer, charged with ammonia and nitric acid, give an impetus to growth, and watering inside borders with the water collected in tanks on rainy days acts similarly. The water dislodges the air and admits fresh, as well as cleanses the soil from impurities where the drainage is thorough. After properly moistening the borders, follow with liquid manure or a top-dressing of fertiliser washed in where the Vines are carrying heavy crops. Sweetened horse droppings are suitable for surfacing heavy soil, farmyard or cow manure answering better for light soils. Do not apply more than an inch or two, and then add to it from time to time so as to keep that thickness, and so supply nutriment regularly. To let the border get dry and so remain at the surface causes the roots to strike down in quest of moisture, and the Grapes often finish badly in consequence.

Regulating the Growth.—Avoid an excess of foliage, and have all the leaves fully exposed to the light. Do not, however, occupy all the space at once with laterals, but leave room for successional growth for encouraging root action. The foliage should be rather thinner in the case of white Grapes than black. Muscats, especially, need the foliage and Grapes well exposed to the light. Avoid large reductions of foliage at one time, the merest point should be taken out of laterals and sub-laterals. Vines extending may be allowed to make as much lateral extension as practicable, but the principal leaves, that nourish the buds to which the Vines are to be pruned, must not be interfered with, affording them full exposure so that they may elaborate the sap, transmit the assimilated matter to the buds, and store food in the adjacent wood. Lateral growth is useful in assisting the canes or main rods to thicken, and this laying on of new layers of wood is important, as by it sap is readily transmitted from the

roots to the growths. Such extension, however, must be kept subordinate to, and not allowed to interfere with, the principal growths, or prevent the access of light and air to the main leaves.

STRAY SWARMS.

MANY stray swarms of bees have been reported from various parts of the country, several swarms having been seen on the wing far away from any apiary. We procured a small cast that was observed hanging from the branch of a tree on the outskirts of a wood. The bees are very black and evidently Punics; these have been isolated in case they have come from a diseased stock.

We have been asked on several occasions how to prevent the absconding of swarms, which more often happens in connection with straw skeps than with the moveable frame hive. In the former, the bees are often restricted for room, the brood nest is small and altogether out of proportion to the laying powers of a young active queen. What is the result? Queen cells are formed, and the first fine day that comes out will come the swarm, flying away without anyone being the wiser. In the case of swarms headed by old queens, they will usually cluster within a few yards of their hive. But with young queens it is altogether different, as when they once get on the wing they will often fly a long distance before alighting.

If bees are kept in frame hives they usually have more space, and are much more under control than when kept in small hives of any description. The remedy is the same in each instance—provide room in advance of the bees' requirements, attend to shading and ventilation, and swarming will be reduced to a minimum.

Swarming is a necessity when bees are kept solely in straw skeps, and if the bee-keeper is not an adept at swarming bees artificially, which, by the way, is such a simple operation that it is surprising anyone should run the risk by allowing the bees to have their own way, when they will probably fly to some hollow tree or an old building and be lost. Such swarms are more common than many people imagine. Within the past few days we have destroyed a strong colony that had had possession of a tree close to a public thoroughfare. The tree was large, and to all appearance sound, and as the bees had become a nuisance to the general public, the hole by which they obtained an entrance was filled with cement, and the bees suffocated.

SWARMING BEES ARTIFICIALLY.

All will depend on the nerve of the operator, his quickness of sight, and his judgment as to the number of bees in the hive, whether the operation will be a success or failure. In the first place he must know when the stock is ready for swarming. With frame hives all that is necessary is to divide a colony into two or more stocks, add the necessary frames, place the hives a few feet on either side of the original stand, cover up warm, and the work is complete.

With straw skeps all that is required is to know when the hive is crowded with bees. This may be done by giving a puff or two of smoke at the entrance, remove the skep from the stand; if the combs are all covered with bees as well as the floorboard, they are then in the right condition for swarming; if, on the contrary, the skep is not well crowded with bees they must remain a few days longer, when they may be again examined.

How often one sees in skeps bees bagging out at the entrance, forming a large cluster half as large as the skep itself. There they will remain for several days or weeks until favourable weather sets in, when they will swarm. During this period but little work is being done, whereas had they been swarmed artificially, and supplied with a small amount of thin syrup daily, they would have half filled a skep with comb, and would have been ready to store a surplus when the fine weather came.

Bees are swarmed artificially similar to the way in which they are driven in the autumn. This has been explained in previous notes. Suffice it to say that the skep to be operated on should be removed from its stand after having had a few puffs of smoke blown in at the entrance. This will cause the bees to fill themselves with honey. Then turn the skep upside down, placing an empty skep on the top. A couple of pieces of bent wire will make some hinges to hold it in position. The operator should sit with his back to the light, so that he has a good view of the bees running up, and that the queen may be seen as she leaves the parent hive with the other bees. Continue drumming the bottom hive with the hands until sufficient bees have ascended. The swarm may then be placed on the old stand, when the bees on the wing on their return home will help to strengthen it. Care must be taken that the old stock is not robbed of too many bees, or it will suffer in consequence. The newly hatched bees will soon replace those which have been taken with the swarm.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

LATE QUESTIONS AND COMMUNICATIONS.—Some communications which arrived when we were preparing for press cannot be inserted this week, and replies to sundry questions must be deferred till the next issue of the JOURNAL OF HORTICULTURE.

Lawn Mowings (P. C. S.).—The short grass removed from lawns is used by some gardeners for mulching—i.e., spreading on the surface of the soil over the roots of vegetable crops and fruit trees for preventing the escape of moisture by evaporation, and thus often doing much good in hot dry weather. We have known the mowings to be spread on the soil in Celery trenches, among Cauliflowers and Lettuce, and along the sides of rows of Peas and Beans, also on the soil near wall and other fruit trees with advantage. Failing such use, the product, when placed in a heap to decay, is good for land that is deficient in vegetable matter. The mowings are not good for placing among Strawberries, as the particles adhere to the ripening fruit.

Melon Leaves Spotted (H. D.).—The leaves are spotted by the rind-rot fungus, *Collitotrichum lagenarium*, which also attacks Kidney Beans and Cucumbers. The best preventive is a rather dry condition of the atmosphere, not necessarily arid, but freely ventilated, so as to prevent the deposition of moisture on the foliage, and not giving more water at the roots than is necessary to keep the plants in health. The seeds also should be examined before sowing, rejecting any that have a dark brown or blackish spot or spots on them; or soak the seeds in water at a temperature of 135° for about five minutes before sowing, and when the plants are up and coming into the second or rough leaf dust them with a preparation of sulphate of copper, such as anti-blight or fostite, and repeat two or three times at intervals of a week or ten days. This will usually prevent its attacking the plants. The best dressing for the soil is lime, using about 2½ per cent., and some little time in advance of the compost being required for use.

Apple Twigs Blighted (A. B.).—The Apple tree shoots have been infested by some caterpillar, which has departed. It appears to have devoured the flowers or centres of the shoots, and may have been one of the many leaf-roller moths. The web may have been that of the small ermine moth caterpillar. The only thing we can suggest is to use early next year a spray of 1 oz. of Paris green in paste, 1 lb. of sulphate of copper, and 2 lbs. of quicklime. Dissolve separately in earthen vessels, and mix well in a wooden tub with 20 gallons of water, strain and apply by means of a knapsack pump when the buds are developing, repeating again before the blossoms unfold. This may destroy the pest and secure a good set of fruit. The twigs are also affected by some fungus, commonly referred to as canker, for which there have been various panaceas, but the fungus in this case can only be got rid of by cutting away the affected portions to sound wood immediately below the dead part. Spraying with the preparation before mentioned will be of service, and in the autumn the trees should be lifted, or if too large for that digging round on one side this year, root-pruning and cutting off any straight down roots. This will check the tendency to the branches dying, treating the other side of the tree similarly the following season. A top-dressing of some approved fertiliser would also be of service, applying shortly after lifting or root-pruning, pointing in lightly and mulching over the roots with short manure.

Liliums (Amateur).—All the Liliums you name have had too much heat, and, moreover, have, perhaps, been at some distance from the glass roof, if not shaded by other plants. We find them the most satisfactory when started in cool frames, the pots plunged at first over their rims in ashes; then when growth is fairly advanced clearing the pots, and top-dressing with rough, rich, loamy soil for inciting stem roots. When the plants are too tall the sashes can be removed, and when the buds are developing the plants may be placed under glass, if needed, for accelerating the expansion or preserving the purity of the blooms. If you remove your plants from under glass now, let them have a shaded position, syringe frequently in dry weather, and take care that they do not suffer by lack of moisture at the roots.

Black Currant Bushes Cropless (A. B.).—The twigs sent are infested with the Currant-bud gall mite (*Phytoptus ribis*), and the pest has destroyed the buds. The mites, however, are not now in the buds, and this is the time to prevent or mitigate further attacks by spraying or syringing the bushes with a solution of petroleum emulsion, wetting them in every part, and repeating again at the beginning of September. The work must be done thoroughly and during a dry time. The petroleum preparation can be procured of any seedsman or horticultural sundriesman, and in using adhere strictly to the instructions. If very badly infested in the autumn, as may be known by the enlarged state of the buds, it would be advisable to cut all away and burn them, but if the treatment advised is followed there may be no need to cut the bushes down. This, as often advised, has only a temporary effect. The point is to kill the mites by the thorough treatment indicated.

Vegetable Marrows Turning Yellow (W. R.).—There must be some particular deficiency in the soil or defect of treatment to cause the fruit to turn yellow instead of swelling in successional order. We should attribute the non-swelling to the plants not having sufficient support. We advise the use of liquid manure liberally in dry weather, and instead of pinching the growths allow them to extend, keeping moderately open rather than crowded. The impregnation is usually effected by insects, but in certain cases it may be necessary to have recourse to artificial means. If ordinary liquid manure, such as that of stables and cow houses, be not at command, you may use a mixture of three parts bone superphosphate, two parts nitrate of potash, and one part gypsum, at the rate of an ounce of the mixture per gallon of water, well mixed and applied clear of the foliage. This may be used about once a week, and with 3 gallons per square yard will be likely to give better results, but do not crowd the growths. The Cucumbers probably do not fruit freely for similar reasons, being too crowded in growth and not supplied with due nourishment.

Apple and Pear Leaves Diseased (J. W.).—On the Apple leaves appear the dark mould, caused by the scab fungus in its early stage, which is very common this season, and disastrous to the foliage of many rosaceous plants. Spray or syringe the trees with a solution of potassium sulphide, 1 oz. to 3 gallons of water, and repeat in about ten days. This will arrest the pest, but the leaves affected will most likely fall at an early date, as they are seriously injured by the parasite. It is a good practice to spray the trees in the early spring, just before the buds commence swelling, with a solution of sulphate of copper, 1 oz. to 1½ gallon of water, just wetting them during a mild dry time. This acts as a preventive, and if the pest appears promptly use the sulphide of potash solution, or better, use it as a preventive just before the trees come into flower, or when the buds are about half expanded, repeating as soon as the first leaves are fairly developed. The Pear leaves are attacked by mites. Spray or syringe them on the under side with a solution of petroleum emulsion, diluting to a safe strength. This will arrest the pests to a certain extent, and thus save the younger leaves from attack. In the autumn syringe the trees with the emulsion during a dry time, from above downwards, so as to reach into the scales of the buds. The emulsion may be used at about double strength then, but in any case attend to the instructions, as to the extent of dilution, supplied with the article, which may be procured of any nurseryman or horticultural sundriesman advertising in our columns.

Raspberries Unsatisfactory (Old Subscriber).—On some chalk formations Raspberries thrive with remarkable vigour, and on others they refuse to grow, which may be due to some peculiar constituent of the soil. Of this we know nothing in your case, only that the "soil is marly over chalk." You do not say whether shallow or what, only "bastard trenched" implies a not very deep soil, therefore we should form trenches as for Celery, and fill them with any vegetable refuse at command, such as that of rubbish heaps, with any soil that can be spared, forming, with refuse potting material, a good vegetable compost, such as frequently accumulates in gardens. Trenches 2 feet wide and deep of such material will usually give good results, but in certain cases the trenches may be mere receptacles for water, and then Raspberries will not grow until means are provided to free it from the stagnant moisture. We have used gravel freely with clayey marl to bring about a better state of things, and then placed the debris of the rubbish heap in ridges on the ground, and on these planted the Raspberries. Then, by mulching with short manure, and improving the staple between the rows, good results have followed. Apples, as a rule, do not thrive on chalk, especially with the kind of surface you describe. It will, perhaps, be necessary to lift the trees and concrete the stations so as to prevent the roots descending, and then form mounds of prepared soil on which to plant the trees afresh. This, with liberal mulching, would probably give the desired results. If wet, drain, and instead of excavating, mix gravel with the marl, forming stations for the trees wholly above the surface. For the Black Currants

we do not see what you need more than some good loam or rubbish heap material to give satisfactory results. Do not be very particular about crocks and the like in the rubbish, for it is mineral matter other than lime the soil requires, a good dressing of ferruginous gravel being of as much importance as the vegetable matter.

Diseased Apple Trees (Exonian).—The cause of the Apple twigs decaying is directly canker, which may be accelerated by the shallow and chalky hungry soil. The fungus has completely girdled the young wood, and the twigs die in consequence of the sap being cut off. Exposed sites, especially on chalk, are not good for Apple trees, and this may have had something to do with the canker, as the growth would probably be free at first through the trees being planted in made soil, and the wood not particularly ripened may have suffered from frost. This origin of the evil appears to date back to at least two winters, perhaps farther, but the collapse is due to the fungus, which probably entered by the frost cracks or "bites." Cut away all the girdled twigs to sound wood, and dress any cankered parts in the autumn with Stockholm tar thinned with petroleum to the consistency of paint, applying to the affected parts only with a half-worn paint brush. Top-dress with short manure now and apply some approved fertiliser. With attention in these respects the trees will probably outgrow the disease. It is important to secure surface roots by summer mulching.

Pests Infesting Beans (Exonian).—The pests are snake millipedes (*Julus pulchellus*), and they, as you say, play havoc amongst Beans, Onions, Turnips, and Potatoes by feeding on the fleshy roots and stems. Dressings of soot are useful in aiding the plants against attacks. Applications of fresh gas lime to the land in autumn usually cleanse the ground from them, but they are fostered in rubbish heaps, and frequently introduced in refuse from them and in manure. The pink-spotted millipede has a fondness for rapemeal, and this we advise for present use, applying 7 lbs. per rod, and after allowing the pests to feed on it for a couple of days dress with nitrate of soda, finely crushed, at the rate of 1 oz. per square yard. There is no occasion to work either the rapemeal or the nitrate of soda into the soil. In the autumn we should dress the land with quicklime, using not less than 5 stones per rod or 5 tons per acre, applying as soon as slaked, and allowing it to lie on the surface a few days before digging in.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Letter Mislaidd*).—1, *Polemonium cœruleum album*; 2, *Polygonum bistorta*; 3, *Veronica gentianoides*; 4, *Astrantia major carinthiaea*; 5, *Veronica teucrium*; 6, *Camelina sativa*. (*P. A.*)—1, *Salvia argentea*; 2, *Pteris serrulata*. (*F. V. F.*)—1, *Cattleya Mendeli*; 2, *Cypripedium Lawrenceanum*. (*D. P.*)—1, *Sambucus aurea variegata*. (*Liverpool Subscriber*).—The specimens are evergreen, *Arbutus Menziesii*; dried truss, *Viburnum tomentosum var. plicatum*; small white flower, *Cistus ladaniferus*. (*J. B.*)—1, One of the many forms of *Athyrium* or *Asplenium filix-femina*; 2, *Valeriana*, species not determinable without leaves; 3, *Selaginella Wildenovi*; 4, *Trachelium cœruleum*; 5, *Euphorbia splendens*.

THE HAYMAKING SEASON.

THE thrifty housewife lives for the future rather than for the present—to-day takes care of itself, to-morrow needs her busy forethought. She may admire a fruitful garden, and mentally weighs and measures the produce. Not much comes in for present use, but the greater part finds its way to the preserving-pan and jelly pots. She sees a large basket of eggs: her instant desire is to plunge them into gallons of pickle. She cannot resist the golden butter of early summer; it goes to her heart to sell it for a small price, and therefore it is found safely stowed away in deep puncheons. The sty of fat pigs suggests noble supplies of lard and toothsome flitches and juicy hams, and she grudges the removal of the necessary trimmings.

It is all very well to laugh at such care and forethought, and condemn it as fussy and tiresome, but the days of plenty do not last for ever, and the cold ungenial seasons come, when we are only too glad of the summer store. And when do we ever find that store too much? Is there a farmer to whom it is not a satisfaction to find that his fodder stacks overlap? Far oftener have we to lament a shortage, and every year we anxiously wonder what we may do to increase our tonnage, knowing full well what a useful—nay, invaluable—thing a bit of good, dry, well got hay will prove to all stock on a mixed occupation.

For many years, beginning about 1878, we had a series of very wet summers, when hay-getting appeared to be a useless pursuit. Then was the time of ensilage—ensilage, that was to prove the perfection of food, and to solve the difficulty. But—like many other universal panaceas—it did not, and after two or three trials most of us came to the conclusion that moderately good hay was superior to ensilage, even of the best quality.

The haymaking season on the great grass farms is a very anxious.

harrassing time. The glass may be at "set fair," and every sign of fine weather. The mowers begin their pleasant task, or on suitable land the grass-cutter will lay swathe after swathe of the fragrant herbage low. The completion of a field generally seems a signal for a break in the weather, and down comes the rain in torrents, and with a relentlessness that is perfectly vindictive. There is nothing to do but to wait, feeling all the time that the soft water is gently drawing all the good out of the grass, and that gallons of capital hay tea are being lost.

The most welcome assistant the farmer has is not so much a burning sun as a brisk drying wind; the sun may be too powerful and take all the nature out, but a good wind does the work more thoroughly and does not detract or extract the valuable properties from the grass. Custom varies much in different counties, even over the process of haymaking, and modern machinery has greatly lessened the mechanical labour. Indeed we do not know where we should find a sufficiency of men able and willing to mow; they only expect to do the rough uneven corners and tiresome bits where the machine can hardly go. There is a time for everything, and it is of material importance that grass should be cut just when it is at its best, and it is most provoking when through stress of unsuitable weather the crop has to stand, and that standing causes hourly deterioration.

The crop say is a light one, possibly owing to lack of moisture or a cold backward season. The farmer cannot possibly spare another acre to "lay in," so he is naturally eager to get the heaviest amount possible. He allows it to stand in the hope of getting better bottom grass, forgetting at the same time that the taller grasses, having flowered, are all past their best, and have reached a stage when their nutritive qualities are practically nil.

The best hay is produced from grass cut before the ripening process has taken place, and the best Clover is made when the plant is almost fully in "knop," and before the bottom leaf begins to fall off. Grass cut too late is deficient in some of its best properties. "All grass in process of time turns to straw, and in doing so the soluble ingredients—sugar, cellulose, and mucilages—become converted partly into woody fibre." After flowering the plant is impoverished, the strength having gone into the seed.

We do not like to see hay too long upon the ground. Well, we may be told, no one does. Possibly not; but for all that there are good people who go about their work not in the handiest and best manner. If the weather look unsatisfactory do not meddle. As long as the freshly cut grass is untouched the rain does not do great harm; it is when half made that the damage is the greatest. Look at a swathe of grass; how close and compact it lies. Shake it about, half make it, and it is left open with no protection against showers.

We prefer, given a suitable day, to manipulate only as much as we can manage to turn over twice. Thus we should work up to dinner time turning and tossing, then begin again and do the same portion over. It is wonderful how quickly hay will "make," and by adopting this plan at any rate all the eggs are not in the same basket. We have a fancy to see hay in "cock" as soon as practicable, believing that in that form it is wonderfully safe from stress of weather. We know this is not a universal custom, but we have proved it to be a good one.

Clover and Sainfoin need very little handling, indeed in handling great damage may be done. It is not the thick strong stems that are of the greatest value, but the juicy knop and the tender leaf. These are easily broken off and destroyed more easily than an amateur would suppose.

It is a very pleasant sight to see the last load safe in the yard, and it is still pleasanter when the stacks are well thatched down, and all danger of "heating" over. A small degree of "sweating" is desirable, but it is an unpleasant surprise to be told that the stacks are rapidly rising in temperature. We fear this oftener occurs in a good hay season than in a damp one. Nature takes her own time to work, and there must be due allowance made for the proper evaporation of sap. "Hasten slowly" is still a good proverb to go by, and much hay and many corn stacks are spoiled by too great hurry.

We believe in "topping" up a stack well before putting on the final thatch. There may always be found on a farm plenty of tough material from hedge bottoms and waste corners, which if properly manipulated will form an excellent protection to the more valuable crop. We are great advocates for cutting up and preserving all sorts of rough bits and storing them with a view to future contingencies. We never know how long winter may last, it is not a season that can be measured by the calendar, and cold winds and sharp frosts often find their way into May and even into June.

WORK ON THE HOME FARM.

Hardly were our notes of last week written and posted before we had an experience, which happily we do not often have in June—it was a really keen frost. As we ourselves lie high and dry, we did not suffer the damage to our Potatoes that we see so sadly prevalent; but already the sudden chill is showing its effect on the Wheat, the hue of which is almost as golden as when harvest is near. We can only hope that this yellow rust will not make itself felt by the presence of mildew later on. We say that we hope, but experience does not give us much encouragement.

Many fields of Potatoes have been very seriously injured along the north-east coast, the haulm being now only a blackened mass. The injury has not been general, but seems to have been local, in a similar way to a thunderstorm. Low wet places have invariably suffered, but dry ground near water has not escaped. There is a curious difference in the effect on different Potatoes. The "Up to Date" variety has shown great susceptibility to frost, and in one case a row of this kind in the midst of a patch of earlies was the only one injured. This seems curious, but we can only account for it on the supposition that the haulm having pushed up quickly would be less hardy than that which had been longer exposed.

Since the frost we have had dry warm weather, but closely followed with a beautiful rain. This is the best thing possible to refresh the cereals after the check, and we are sure to see very considerable benefit therefrom.

Turnips also must now do well, and we hear no further complaints of fly. Hoeing and singling will soon be the staple work of the farm, alternated of course with the necessary periods of haymaking.

We are dipping our sheep, both lambs and ewes; the ewes take very little doing now, and if all are done at once, and again in September, there should be no further trouble from insect parasites.

REMARKS.

- 12th.—Cold, with leaden sky throughout.
 13th.—Overcast and cold.
 14th.—Overcast morning; fair afternoon, but sunless.
 15th.—Overcast early; frequently sunny after 10.30, and bright from 3 P.M.
 16th.—Overcast till 10.30 A.M.; bright sun in afternoon.
 17th.—Much cloud, but sunny at times, especially in afternoon.
 18th.—A perfect June day, but a shower between 8 and 9 P.M.
 A cold, and but for the last two days, a very cold week. Practically no rain
 19th.—Overcast early, but generally sunny after 11 A.M.
 20th.—Generally overcast till 9.30 A.M. and after noon; frequent sun in morning.
 21st.—Overcast early, and frequent cloud in morning; bright sun in afternoon.
 22nd.—A sprinkle of rain about 4 A.M.; frequent cloud in morning, bright sun after.
 23rd.—Bright and fresh day; overcast evening.
 24th.—Cold and dull, with rain or drizzle almost all the morning.
 25th.—Alternate sunshine and storm rains in morning; generally cloudy after, with spots of rain.
 A week of average temperature and rainfall.—G. J. SYMONS.
